Growth and Labor Market Churning: Role of Vertical versus Horizontal Innovation

Job Market Paper

November, 2021

Hyejin Park

This paper: Labor Market Churning and Growth

- Labor reallocation from low to high productivity firms is an essential component of productivity growth.

This paper: Labor Market Churning and Growth

- Labor reallocation from low to high productivity firms is an essential component of productivity growth.
- Consequently, labor market churning is often used as a diagnosis tool for aggregate economic performances.

This paper: Labor Market Churning and Growth

- Labor reallocation from low to high productivity firms is an essential component of productivity growth.
- Consequently, labor market churning is often used as a diagnosis tool for aggregate economic performances.
- This relation depends on who makes the innovation.

– **Vertical Innovation**:
Innovation by firms currently existent in the market
$\Rightarrow$ Growth w/o firm replacements

– **Horizontal Innovation**:
Innovation by firms new to the market
$\Rightarrow$ Growth w/ firm replacements

This paper: Labor Market Churning and Growth

- Labor reallocation from low to high productivity firms is an essential component of productivity growth.
- Consequently, labor market churning is often used as a diagnosis tool for aggregate economic performances.
- This relation depends on who makes the innovation.

– **Vertical Innovation**:
Innovation by firms currently existent in the market
$\Rightarrow$ Growth w/o firm replacements

– **Horizontal Innovation**:
Innovation by firms new to the market
$\Rightarrow$ Growth w/ firm replacements

- However, this distinction is not often made within a unified framework due to difficulty of isolating these two innovations.

Examples of Vertical and Horizontal Innovations

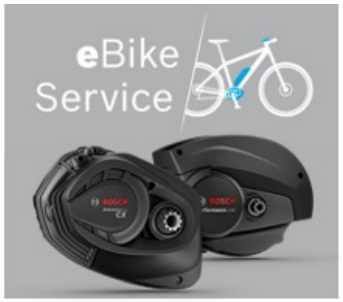
VS

Vertical Innovation

Generations of Hand Drills by Bosch

- Replaces its own product
- Small net labor churning

BOSCH +



Horizontal Innovation

Bosch's expansion to E-Bike Motors

- Replaces others' products
- Large net labor churning

Identifying Innovation through Survey Questions

- **Vertical Innovation**:
  - – Did your establishment improve or further develop a product or service which had previously been part of your portfolio?
  - & Did you develop or implement procedures which have noticeably improved production processes or services?

Innovation - Details

Identifying Innovation through Survey Questions

- **Vertical Innovation**:
  - Did your establishment improve or further develop a product or service which had previously been part of your portfolio?
  - & Did you develop or implement procedures which have noticeably improved production processes or services?
  - ⇒ Productivity improvement within a product line

Innovation - Details

Identifying Innovation through Survey Questions

- **Vertical Innovation**:
  - Did your establishment improve or further develop a product or service which had previously been part of your portfolio?
  - & Did you develop or implement procedures which have noticeably improved production processes or services?
  - ⇒ Productivity improvement within a product line
- **Horizontal Innovation**:
  - Did your establishment start to offer a product/service new to the establishment?

  - – Did your establishment start to offer a product/service new to the establishment?
  - ⇒ Expansion to a new product line
  - ⇒ Productivity improvement through reallocation of product lines

Innovation - Details

Research Question

- **Research Question**:
  - Does labor market churning increase with aggregate growth?
  - How do vertical & horizontal innovations affect labor market churning?

Research Question

- **Research Question**:
  - Does labor market churning increase with aggregate growth?
  - How do vertical & horizontal innovations affect labor market churning?
- **Findings**:
  - Vertical innovation churns labor less than horizontal innovation.
  - Vertical innovation accounts for most productivity growth.
  - $\Rightarrow$ Labor market churning does not respond elastically to aggregate growth.

Research Question

- **Research Question**:
  - Does labor market churning increase with aggregate growth?
  - How do vertical & horizontal innovations affect labor market churning?
- **Findings**:
  - Vertical innovation churns labor less than horizontal innovation.
  - Vertical innovation accounts for most productivity growth.
  - $\Rightarrow$ Labor market churning does not respond elastically to aggregate growth.
- **Application**:
  - The Hartz labor market reform improves productivity growth and welfare additionally through more vertical innovation.
  - Job destruction rates do not increase after the reform.

Literature Review

New Facts from Survey Measure

German Establishment Panel Survey (IAB-BP)

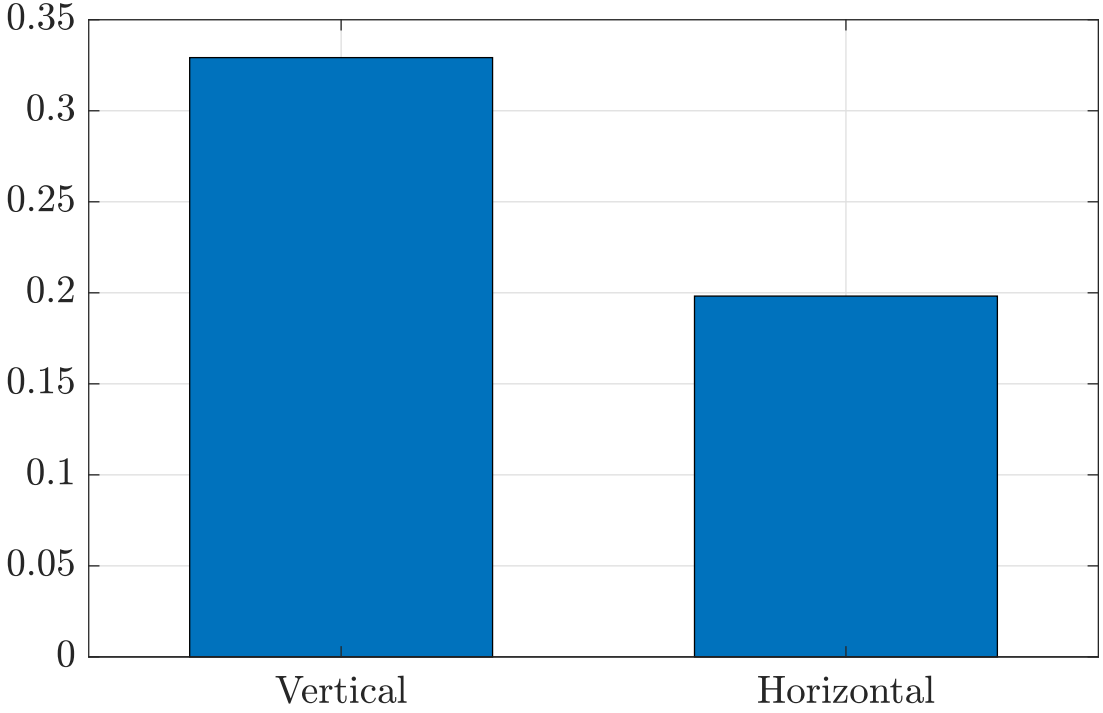
- Annual survey of establishments in Germany.
- Coverage
  - Starts in 1993 for West Germany and 1996 for East Germany, currently until 2017.
  - Representative random sample stratified according to establishment size, industry, and federal state.
  - Approximately 16,000 establishments per year.
- Innovation module started in the 2008 survey.
- Substantial changes in covered variables and questions in 2002.

  $\Rightarrow$ Restrict my samples to the post-2002 period.
- IAB-BP can be linked to the administrative employer-employee matched data.
  - Employment, Imputed daily wage of full time employees as of June 30.

Data Description Comparison to Patent Data

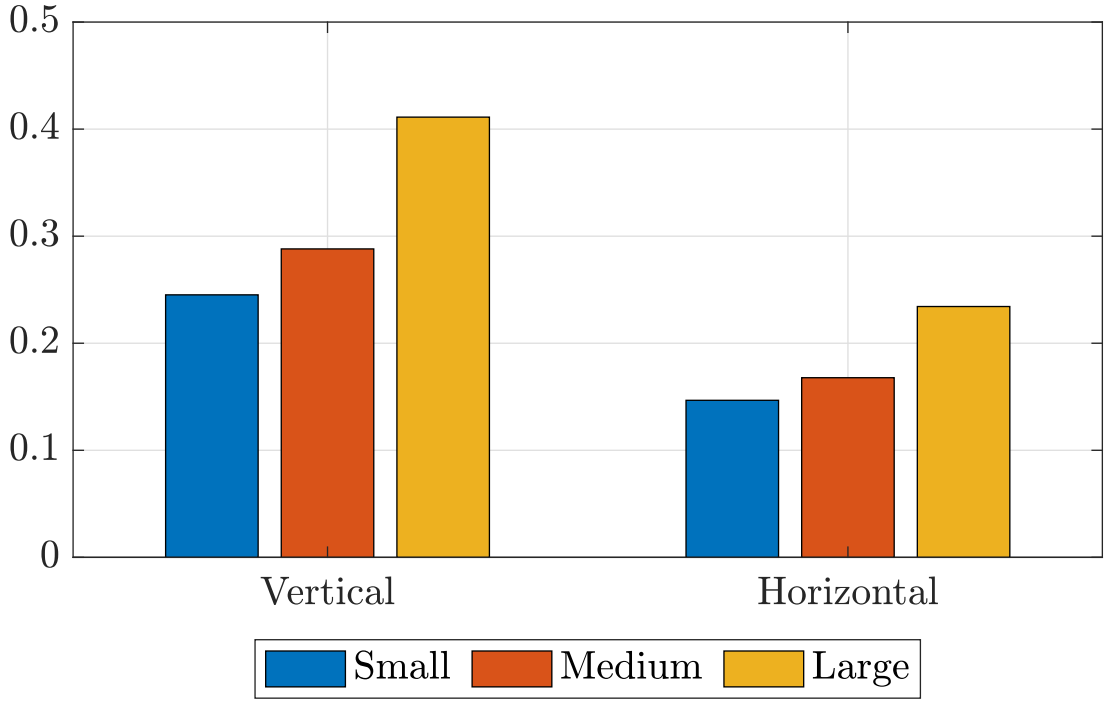
Fraction of Innovating Establishments

- More firms innovating vertically than horizontally.



Lagged Size and Fraction of Innovating Est.

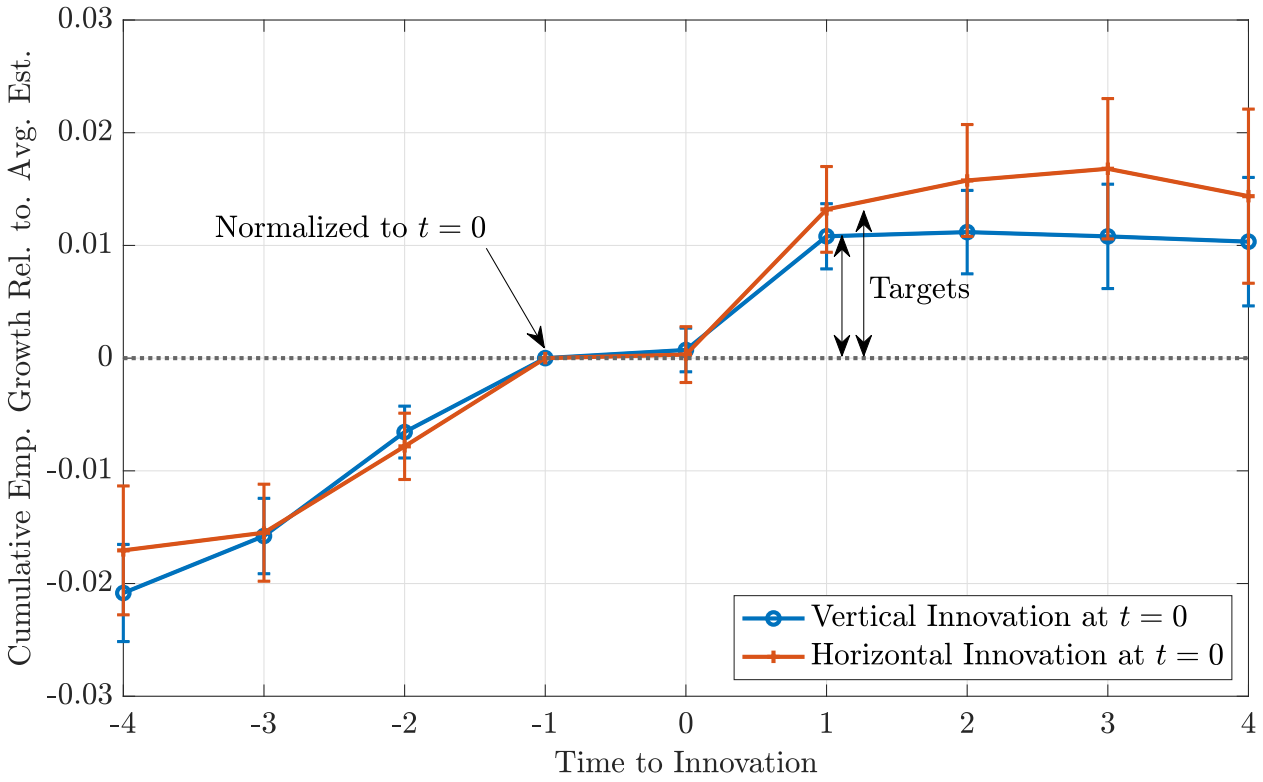
- Larger establishments are more likely to innovate.



Innovation and Employment Growth

- Innovating firms grow faster relative to the average establishment.

⇒ Labor churning from job creation.



Innovation Dynamics

Summary of Regression Exercise

- Innovating establishments
  - after controlling for est. f.e. and other innovations
  - Vertical innovation ⇒ smaller and temporary increase in emp.
  - Horizontal innovation ⇒ larger and persistent increase in emp.

Regression Results

Summary of Regression Exercise

- Innovating establishments Regression Results
  - after controlling for est. f.e. and other innovations
  - Vertical innovation ⇒ smaller and temporary increase in emp.
  - Horizontal innovation ⇒ larger and persistent increase in emp.
- Non-Innovating establishments Regression Results
  - after controlling for industry f.e. and other innovations
  - Vertical innovation by competitors ⇒ small decrease in emp.
  - Horizontal innovation by competitors ⇒ large decrease in emp.

Summary of Regression Exercise

- Innovating establishments Regression Results
  - after controlling for est. f.e. and other innovations
  - Vertical innovation $\Rightarrow$ smaller and temporary increase in emp.
  - Horizontal innovation $\Rightarrow$ larger and persistent increase in emp.
- Non-Innovating establishments Regression Results
  - after controlling for industry f.e. and other innovations
  - Vertical innovation by competitors $\Rightarrow$ small decrease in emp.
  - Horizontal innovation by competitors $\Rightarrow$ large decrease in emp.
- Vertical innov. $\Rightarrow$ within-line productivity $\Uparrow$ $\Rightarrow$ small size $\Uparrow$, no direct dest.
  Horizontal innov. $\Rightarrow$ additional product line $\Rightarrow$ large size $\Uparrow$, creative dest.

Other Regression Results

Model

Model - Overview

- **Goal**
  - Construct a framework to quantify the impact of firm innovation behavior on macro outcomes such as growth and job flow rates.
  - Incorporate endogenous horizontal and vertical innovation choices into the BGP à la Acemoglu and Cao (2015) and Akcigit and Kerr (2018).
- **Agents**
  - Representative households consume final goods and supply labor.
  - Competitive final good producers combine intermediate inputs.
  - Intermediate good producers hire workers & innovate vertically and horizontally on multiple product lines.
- **Technology**
  - A product line produces intermediate inputs using labor.
  - Intermediate inputs are differentiated & aggregated with CES.

Final Good Production and Factor Demand

- The final good is produced by

$$Y_t = \left(\int_0^1 a_{jt} y_{jt}^{\frac{\sigma-1}{\sigma}} dj \right)^{\frac{\sigma}{\sigma-1}},$$

where $\sigma > 1$ is the elasticity of substitution.

- An intermediate good producer solves

$$p_{jt} = \arg\max_p \left\{ y_{jt}(p)p - y_{jt}(p)W_t \right\}.$$

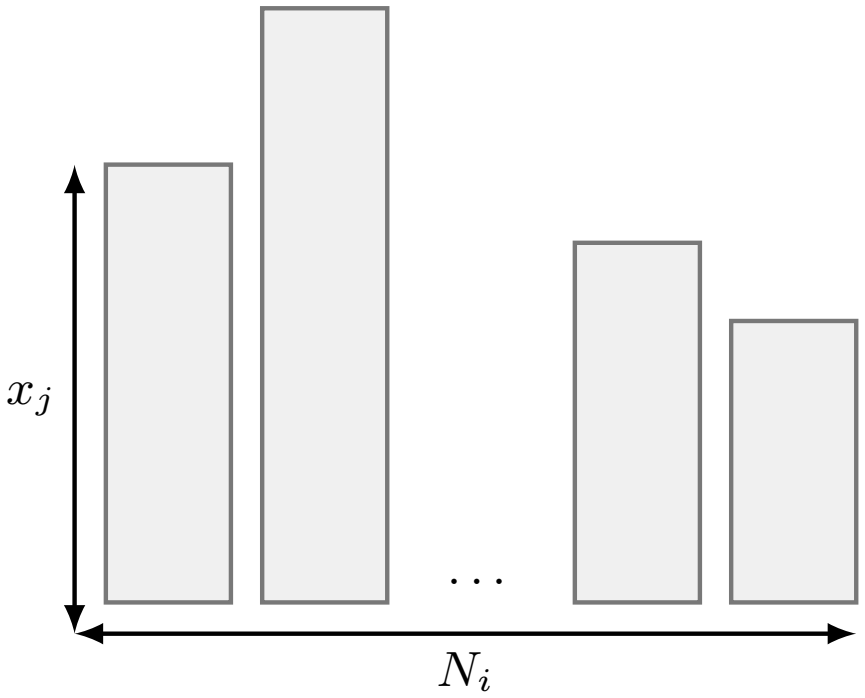
- The solution gives the following profit and production labor demand.

$$Y_t \pi(x_{jt}) := Y_t x_{jt}/\sigma, \quad W_t l^p(x_{jt}) = (\sigma - 1) Y_t x_{jt}/\sigma$$

where $x_{jt} := a_{jt}^{\sigma} / A_t^{\sigma-1}$ and $A_t := \left(\int_0^1 a_{jt}^{\sigma} dj \right)^{\frac{1}{\sigma-1}}$.

- For the zero-profit of final goods producers, $W_t = A_t \frac{\sigma-1}{\sigma}$.

Graphics: Revenue and Depreciation

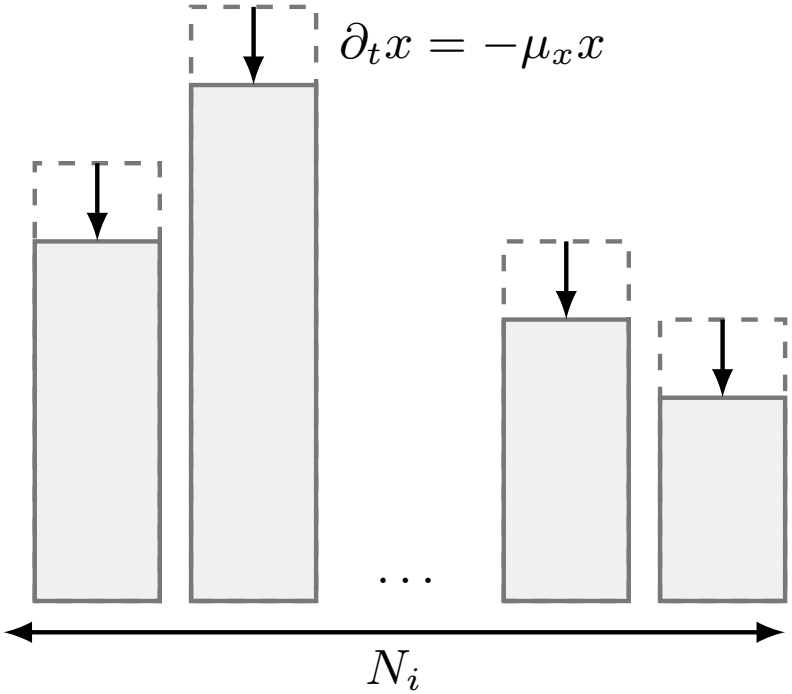


- Firm state $= \{x_j\}_{j=1}^{N_i}$.
  N_i - number of product lines
  x_j - relative quality
- Without any firm-level shock,

$\Rightarrow$ x depreciates over time with A_t growing over time.

$\Rightarrow$ Nothing happens to N_i.

Graphics: Revenue and Depreciation

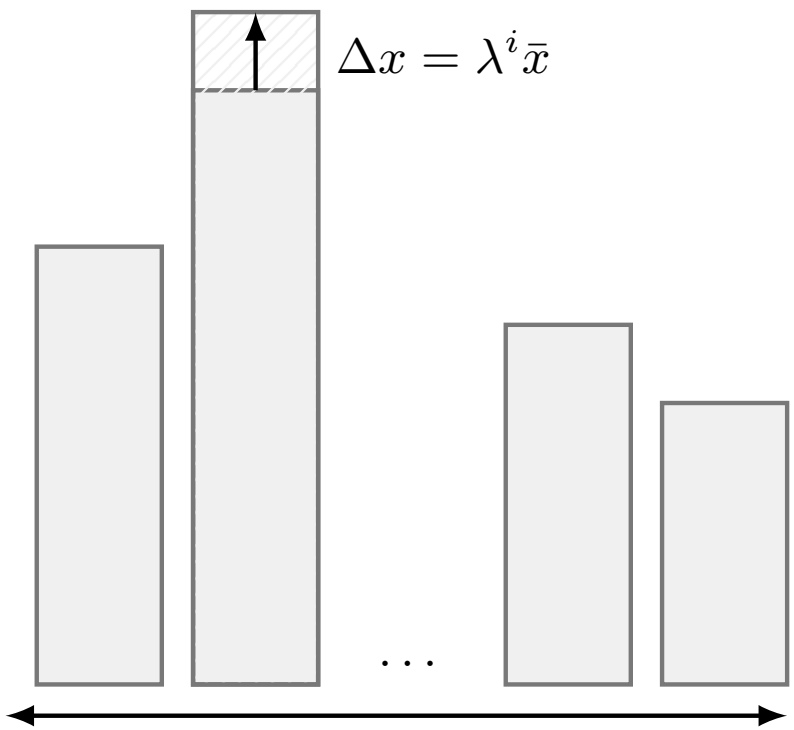


- Firm state $= \{x_j\}_{j=1}^{N_i}$.
  N_i - number of product lines
  x_j - relative quality
- Without any firm-level shock,

$\Rightarrow$ x depreciates over time with A_t growing over time.

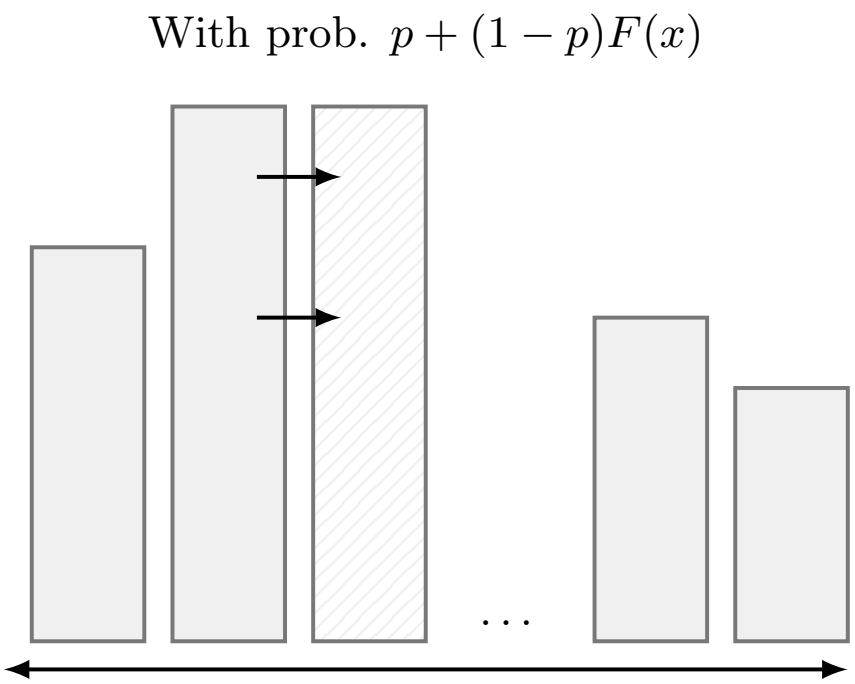
$\Rightarrow$ Nothing happens to N_i.

Graphics: Vertical Innovation



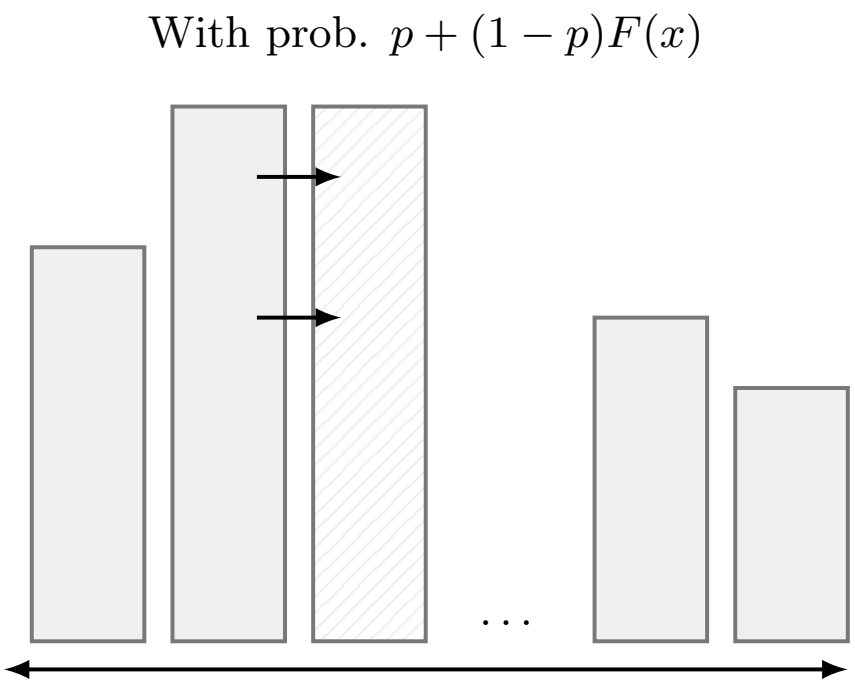
- A firm can vertically innovate with a Poisson rate ξ at the labor cost of $W_t c_\xi(\xi)$.
- Vertical innovation choice is product-line-specific.
- $c'_\xi, c''_\xi > 0$
- Vertical innovation increases relative productivity of a product line by $\lambda^i \bar{x}$.

Graphics: Horizontal Innovation



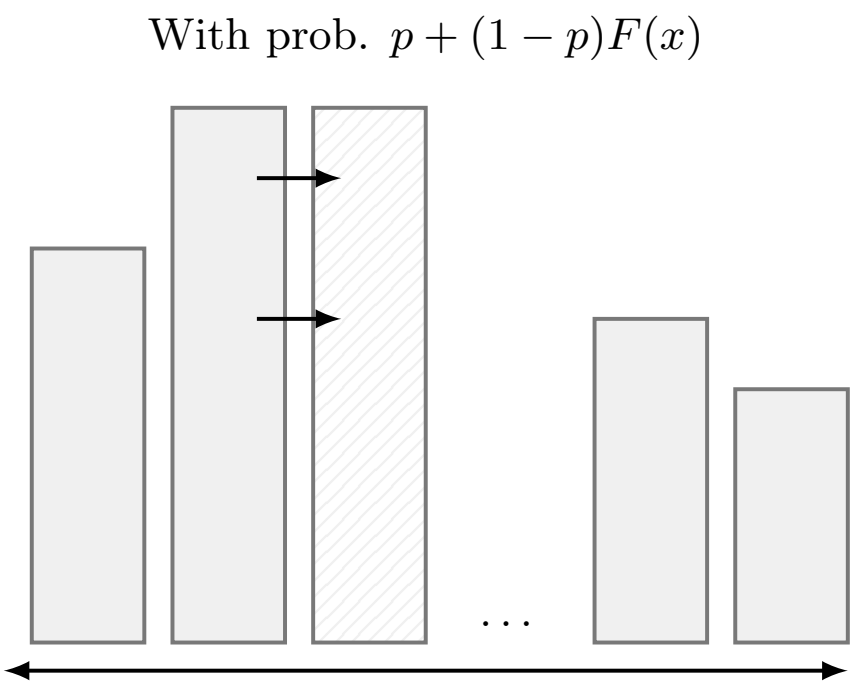
- A firm can horizontally innovate with a Poisson rate ζ at the labor cost of $W_t c_\zeta(\zeta)$.
- Horizontal innovation adds a new product line having the same productivity.
- With probability p, it is matched to a vacant product line.

Graphics: Horizontal Innovation



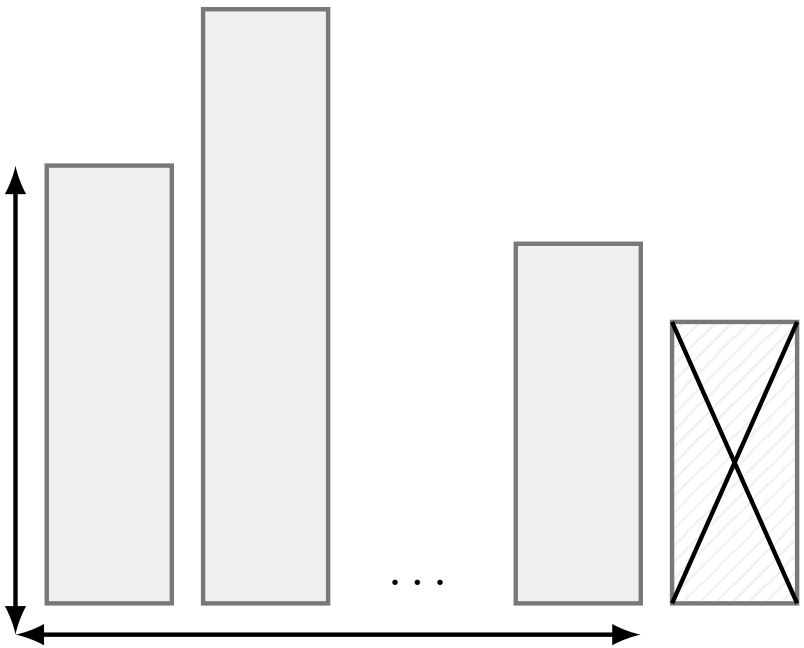
- A firm can horizontally innovate with a Poisson rate ζ at the labor cost of $W_t c_\zeta(\zeta)$.
- Horizontal innovation adds a new product line having the same productivity.
- With probability p, it is matched to a vacant product line.

Graphics: Horizontal Innovation



- A firm can horizontally innovate with a Poisson rate ζ at the labor cost of $W_t c_\zeta(\zeta)$.
- Horizontal innovation adds a new product line having the same productivity.
- With probability $1-p$, it is matched to an occupied product line.
- It must be more productive than the matched firm for prod.

Graphics: Creative Destruction



- A creative destruction shock at rate $\tau(x)$.
- Matched firms replace old firms if they are more productive.

$\Rightarrow$ $\tau'(x) < 0$.

- Horizontal & entrant innovation

$\Rightarrow$ creative destruction shock.

More Graphical Illustration

Firm Values and Stationary Value

- The profits are summed over product lines.
- All decisions & shocks independent across product lines (except exits).

$\Rightarrow$ Firm value = sum of product line values.

$$\mathfrak{V}_t\left(\{x_j\}_{j=1}^{N_i}\right) = \sum_{j=1}^{N_i} V_t\left(x_j\right)$$

- On the BGP, all input prices, output, and profits grow at g_Y.

$\Rightarrow$ $v_t(x) := V_t(x)/Y_t$ is a time-invariant function of x.

Firm and Product Line Values

- The stationary component of a product line value

$$
\begin{aligned}
(\rho+\delta+\tau(x))\,v(x) = \max_{\xi,\zeta\geq 0}\Bigg\{ & \underbrace{\pi(x)}_{\text{profit}} - \underbrace{g_x x v'(x)}_{\text{depreciation}} \\
& - wc_\xi(\xi) + \xi \underbrace{\left(v\left(x+\lambda^i\bar{x}\right) - v(x)\right)}_{\text{return to V.I.: better quality}} \\
& - wc_\zeta(\zeta) + \zeta \underbrace{(p+(1-p)F(x))\,v(x)}_{\text{return to H.I.: additional line}} \\
& - (\tau(x)+\delta)\,\kappa x \Bigg\}.
\end{aligned}
$$

where wc_ξ and wc_ζ are the labor costs of vertical and horizontal innovation.

Definition of BGP Equilibrium

- The Balanced Growth Path (BGP) equilibrium is defined as value function $v(x)$; policy function $\xi(x)$, $\zeta(x)$; product line distribution $f(x)$; creative destruction rates $\tau(x)$; growth rates μ_x, μ_Y; entry rate χ; constant wage level w; a constant interest rate r; the constant labor supply L such that

  1. The representative household optimizes.
  2. Value function and policy function satisfy the HJB equations.
  3. The distribution of product lines over x stays constant. The mass of product lines is also time-invariant.
  4. The free entry condition is met to pin down entry rate, χ.
  5. Growth and creative destruction rates are time-invariant.
  6. Final goods and labor markets are cleared.

RepH Distribution Creative Destruction Free Entry & Labor Market Clearing

Product-line Innovation and Churning

- Suppose vertical innovation happens to a product line with x.
  - Increase in the productivity of a product line: $\lambda^i \bar{x}$.
  - Job creation of the innovating firm:

$$\lambda^i \bar{x} \frac{(\sigma - 1)}{w\sigma} + (c_\zeta(x + \lambda^i \bar{x}) - c_\zeta(x)) + (c_\xi(x + \lambda^i \bar{x}) - c_\xi(x))$$

  - Job destruction of non-innovating firms:

$$\underbrace{g_x \tilde{x} \left(\frac{(\sigma - 1)}{w\sigma} + c'_\zeta(\tilde{x}) + c'_\xi(\tilde{x}) \right)}_{\text{Obsolescence}}$$

Product-line Innovation and Churning

- Horizontal innovation & creative destruction
  - Assume the same productivity increase: $\lambda^i \bar{x}$
  - Job creation of the innovating firm:

$$\frac{x(\sigma-1)}{w\sigma} + \lambda^i \bar{x} \frac{(\sigma-1)}{w\sigma} + c_\zeta(x + \lambda^i \bar{x}) + c_\xi(x + \lambda^i \bar{x})$$

  - Job destruction of non-innovating firms:

$$\text{Obsolescence} + \underbrace{\frac{x(\sigma-1)}{w\sigma} + c_\zeta(x) + c_\xi(x)}_{\text{Creative Destruction}}$$

Product-line Innovation and Churning

- For the same productivity increase,
  horizontal innovation reallocates more labor *across* firms by

$$l(x) := \frac{x(\sigma - 1)}{w\sigma} + c_\zeta(x) + c_\xi(x)$$

- $l(x)$ = labor demand of a product line with x.

Aggregate Job Creation

- For a sufficiently small Δ, job creation happens in three cases
  - Vertical Innovation: job creation by $l(x+\lambda^i\bar{x}) - l(x) - \Delta g_x x l'(x)$
  - Horizontal Innovation: job creation by $l(x) - \Delta g_x x l'(x)$
  - Entry: job creation by $l(x+\lambda^e\bar{x})$
- Average job creation rate is approximately

$$\int \xi(x)(l(x+\lambda^i\bar{x}) - l(x) - \Delta g_x x l'(x))dF(x)$$
$$+\int \zeta(x)(p+(1-p)F(x))(l(x) - \Delta g_x x l'(x))dF(x)$$
$$+\chi\int (p+(1-p)F(x+\lambda^e\bar{x}))l(x+\lambda^e\bar{x})dF(x)$$

- Increase in ξ, ζ (Job creation $\Uparrow$) $\Rightarrow$ $g_x \uparrow$ (Job creation $\Downarrow$)
- Quantitatively, ζ creates more job creation for a fixed Δg_x.

Aggregate Job destruction

- Likewise, job destruction happens in three cases
  - Exit: job destruction by $l(x)$
  - Creative Destruction: job destruction by $l(x)$
  - Nothing: job destruction by $\Delta g_x x l'(x)$
- Average job destruction rate is approximately

$$\int (\tau(x) + \delta) l(x) dF(x) + \int (1 - \bar{\zeta} - \bar{\xi} - \bar{\chi} - \bar{\tau} - \delta) \Delta g_x x l'(x) dF(x)$$

$\bar{\xi} := \int \xi(x) dF(x)$ and $\bar{\zeta} = \int \zeta(x)(p + (1-p)F(x)) dF(x)$ are the mass of vertically and horizontally innovating establishments, respectively.

- Increase in ξ, ζ (Job Destruction $\Downarrow$) $\Rightarrow g_x \uparrow$ (Job Destruction $\Uparrow$)
- Increase in $\zeta \Rightarrow \tau \uparrow$ (Job Destruction $\Uparrow$)

Calibration

Calibration - Step 1

- Iso-elastic innovation cost functions

$$c_\xi(\xi) = c_\xi \frac{\epsilon_\xi}{\epsilon_\xi + 1} \xi^{\frac{\epsilon_\xi + 1}{\epsilon_\xi}}$$

$$c_\zeta(\zeta) = c_\zeta \frac{\epsilon_\zeta}{\epsilon_\zeta + 1} \zeta^{\frac{\epsilon_\zeta + 1}{\epsilon_\zeta}}$$

$$c_\chi(\chi) = c_\chi \chi^{\frac{\epsilon_\chi + 1}{\epsilon_\chi}}$$

- q^v, q^h: prob. of successful innov. conditional on survey 'yes'.
- Within firm, independent innovation events across product-lines.
- Two model parameters externally matched. One for normalization.

Moment	Meaning	Value	Source
r	Discount rate	8%/12	Average Stock Market Rate of Return
δ	Exogenous exit rate	1%/12	Fackler et al. (2013)
$\bar{L}$	Labor supply in the steady state	0.38	Normalization ($w = 1$)

Calibration - Step 2

- 10 moments matched for 10 parameters

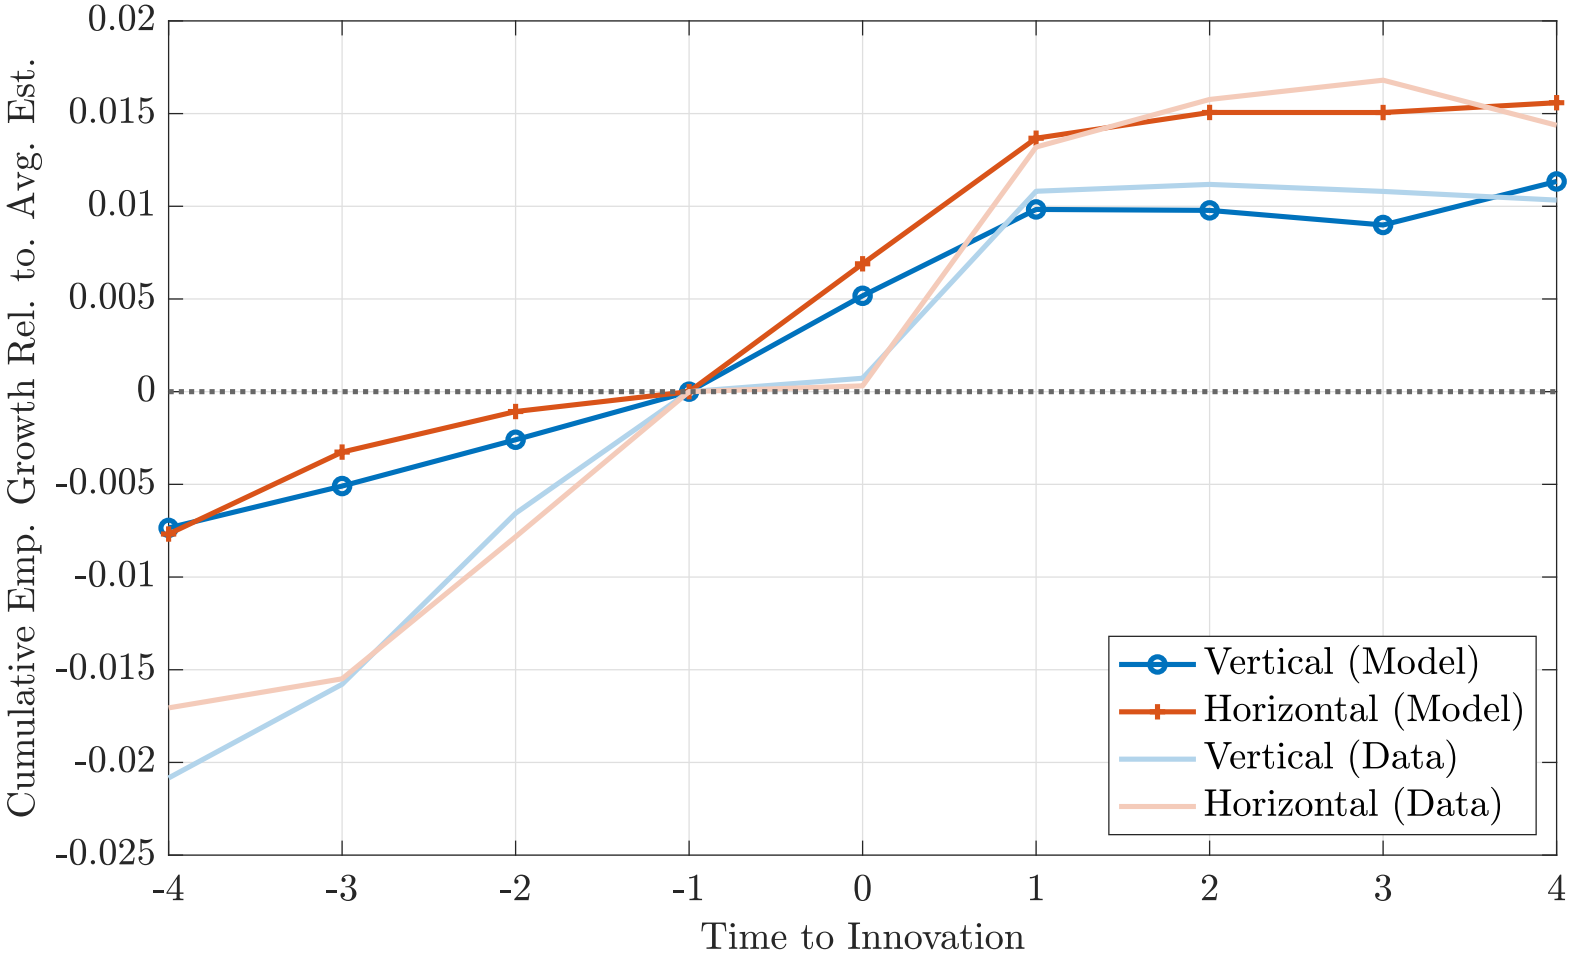
Moment	Data	Model	Target
Annual Growth Rate	1.34%	1.30%	λ^i
Frac. of Vertical Innov.	29.4%	29.4%	c_ξ
Frac. of Horizontal Innov.	17.3%	17.4%	c_ζ
Verti. Innov. Frac. Diff. across Size 2T and 1T	3.6%p	3.4%p	ϵ_ξ
Horiz. Innov. Frac. Diff. across Size 2T and 1T	2.0%p	1.3%p	ϵ_ζ
2-year Size Gr. after Verti. Innov. Rel. Avg.	1.08%p	1.08%p	q^v
2-year Size Gr. after Horiz. Innov. Rel. Avg.	1.32%p	1.35%p	q^h
2-year Size Gr. w/o Innov. Rel. Avg.	-1.55%p	-1.43%p	σ
Employment Share of Establishment Age ≤ 1	1.08%	1.51%	λ^e
Establishment Share of Establishment Age ≤ 1	1.9%	1.9%	χ

Calibration Results

	Parameter	Value
λ^i	Step Size of Vertical Innovation	2.72%
λ^e	Step Size of Entrant Innovation	3.09%
σ	Elasticity of Substitution across Prod. Lines	1.39
c_ξ	Vertical Innovation Cost Shifter	2038.85
ϵ_ξ	Vertical Innovation Cost Elasticity	0.53
c_ζ	Horizontal Innovation Cost Shifter	2.61e+06
ϵ_ζ	Horizontal Innovation Cost Elasticity	0.31
$12 \times \chi$	Annual Share of Entrant Draws	0.92%
q^h	Probability of Successful Expansion	3.12%
q^v	Probability of Successful Improvement	55.00%

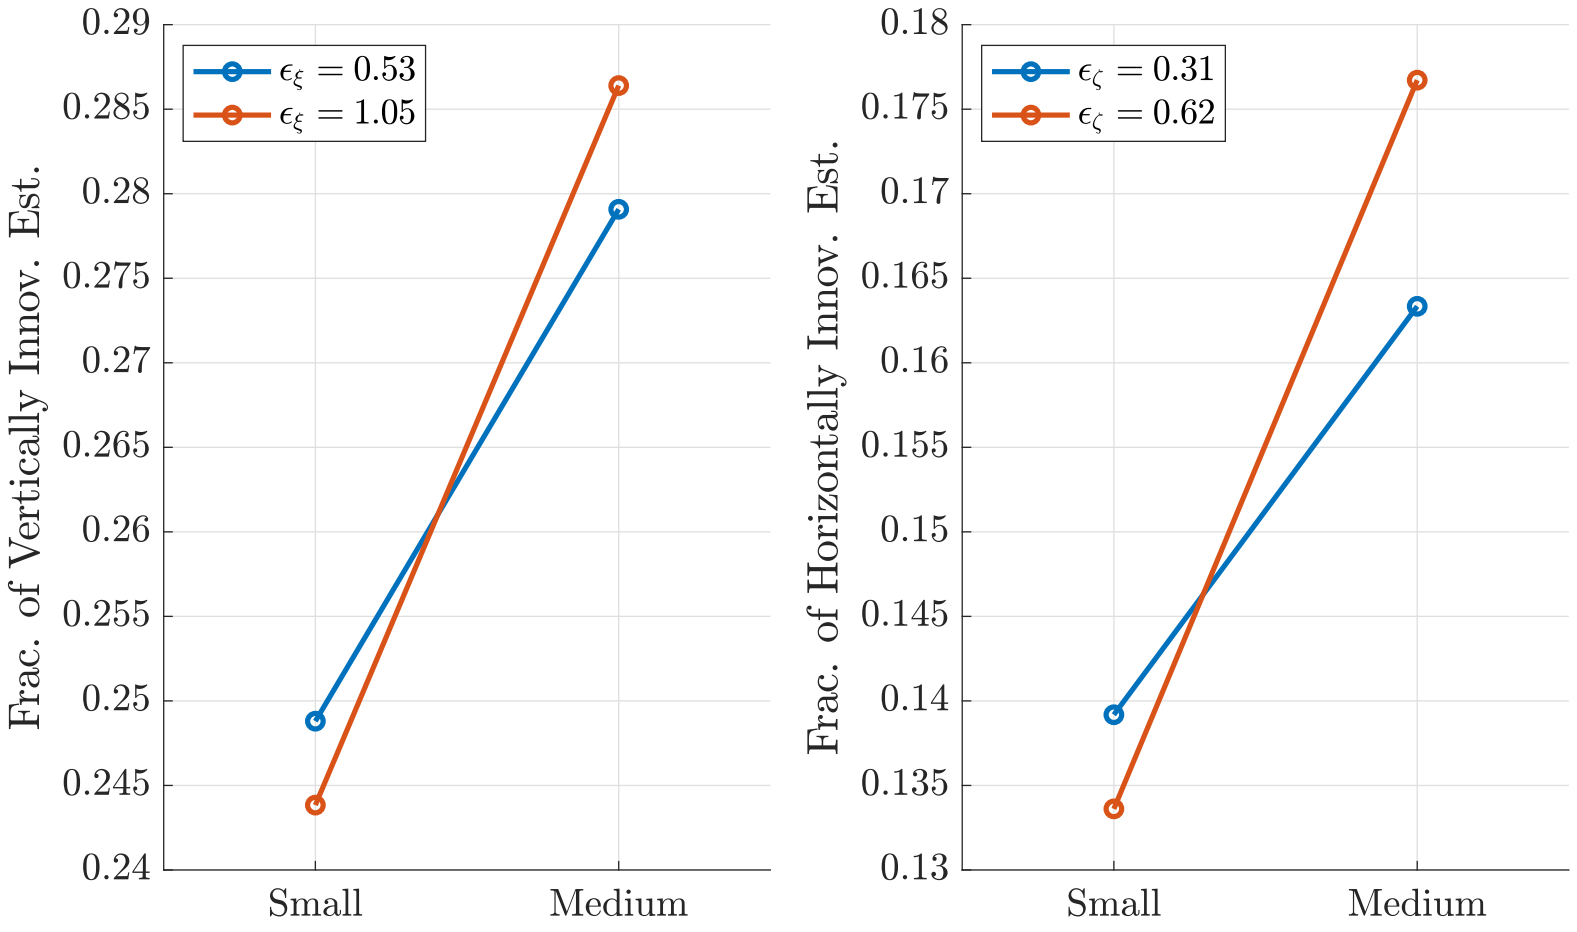
Model Fit

Dynamic Correlation with Innovation



Identification of ϵ_ζ and ϵ_ξ

- A higher elasticity $\Rightarrow$ a steeper size profile of innovation frac.



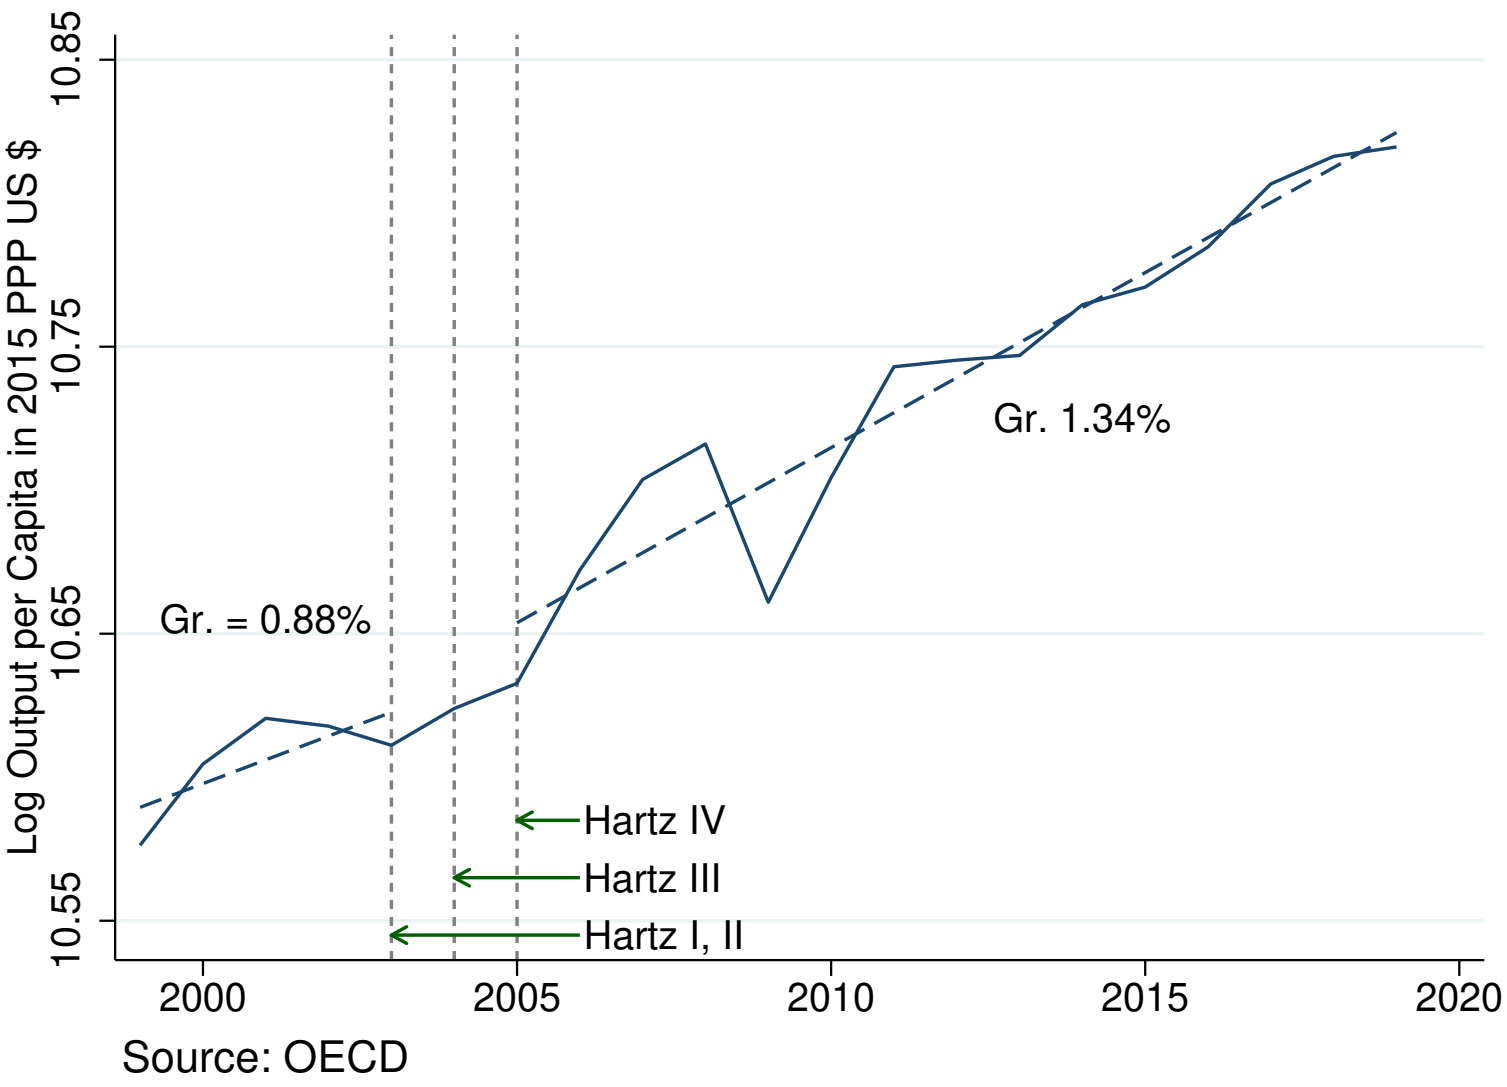
Counterfactual Analysis

Counterfactual Analysis

- I focus on the Hartz Reform today.
  - Steady State with and without the policy introduction
    $\Rightarrow$ Impacts on growth and job turnover rates in S-S.
  - Transition from the baseline BGP to the new BGP after the policy introduction
    $\Rightarrow$ Welfare Analysis
- Three Major components of Hartz Reform (Jacobi and Kluve, 2006)
  1. improving employment services and policy measures
  2. activating the unemployed
  3. fostering employment demand by deregulating the labour market

Other Counterfactuals

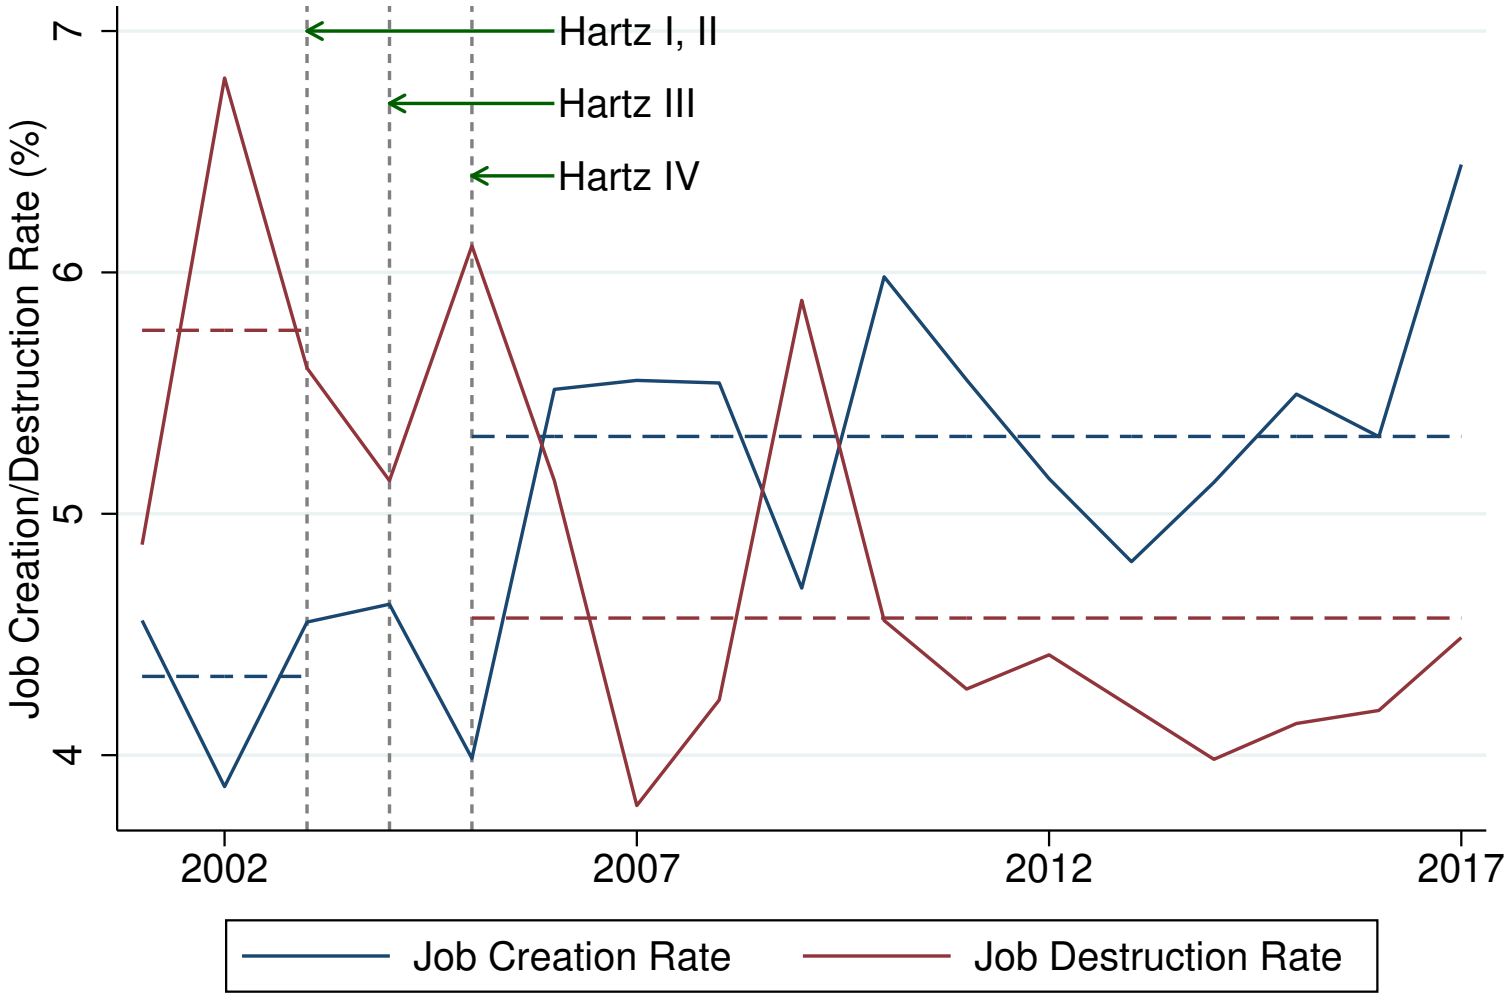
Labor Market Reform and GDP growth in Germany



Labor Market Reform and Employment

Source: OECD ALFS

Labor Market Reform and Job Turnover



Source: Author's Calculation from IAB–BP Microdata

The Hartz Reform: Aggregate Moments

- Reduction in labor wedge ω_L and firing cost parameter, κ.
- Changes in labor wedge to match the actual increase in employment.
- Decrease in κ to match the average firing cost.
- Frisch elasticity of labor supply = 1, entry elasticity = 0.1

Moment	Pre	$\omega_L = 0$	$\kappa = 0$	Post
Annual Output Growth Rate	1.23%	1.30%	1.23%	1.30%
Wage	1.0975	0.9987	1.0989	1.0000
R&D Labor Share	29.20%	27.37%	29.22%	27.39%
Avg. Annual Job Reallocation Rate	1.73%	1.73%	1.73%	1.73%
Avg. Annual Vertical Innov. Freq.	16.06%	16.85%	16.11%	16.88%
Avg. Annual Horizontal Innov. Freq.	0.52%	0.53%	0.52%	0.53%

Alternative Elasticity Values

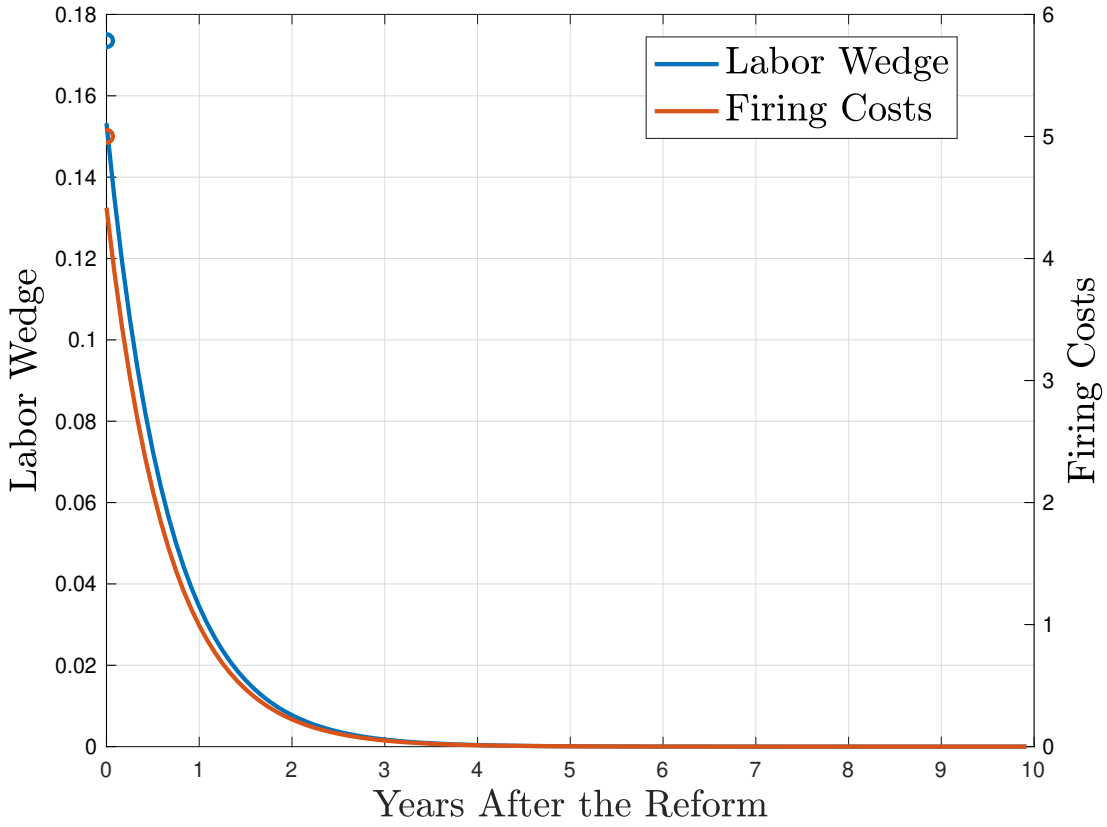
The Hartz Reform: Decomposition

- Almost all growth from vertical innovation.
- However, most job creation from horizontal and entrant innovations.

Moment	Pre	$\omega_L = 0$	$\kappa = 0$	Post
Job Creation Due to Verti. Innov.	25.42%	26.21%	25.46%	26.21%
Job Creation Due to Horiz. Innov.	26.79%	26.81%	26.79%	26.84%
Job Creation Due to Entr. Innov.	47.80%	46.97%	47.75%	46.95%
Job Dest. Due to Creative Dest.	12.45%	13.11%	12.51%	13.15%
Job Dest. Due to Q. Depreciation	29.84%	29.09%	29.81%	29.05%
Job Dest. Due to Exog. Exit	57.71%	57.80%	57.69%	57.80%
Verti. Innov. Contri. to Growth	91.29%	90.46%	91.75%	90.78%
Horiz. Innov. Contri. to Growth	2.61%	2.87%	2.48%	2.81%
Entr. Innov. Contri. to Growth	6.09%	6.67%	5.77%	6.41%

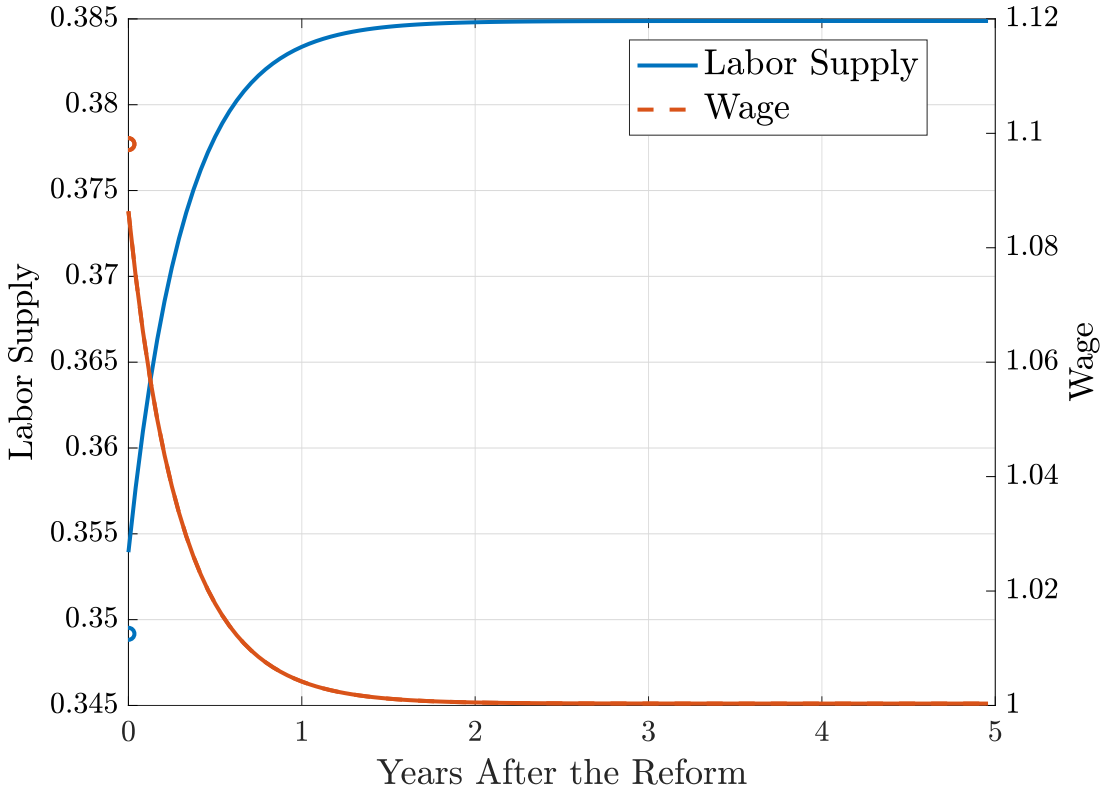
The Hartz Reform: Transition

- Smooth Decrease in ω_L and κ.



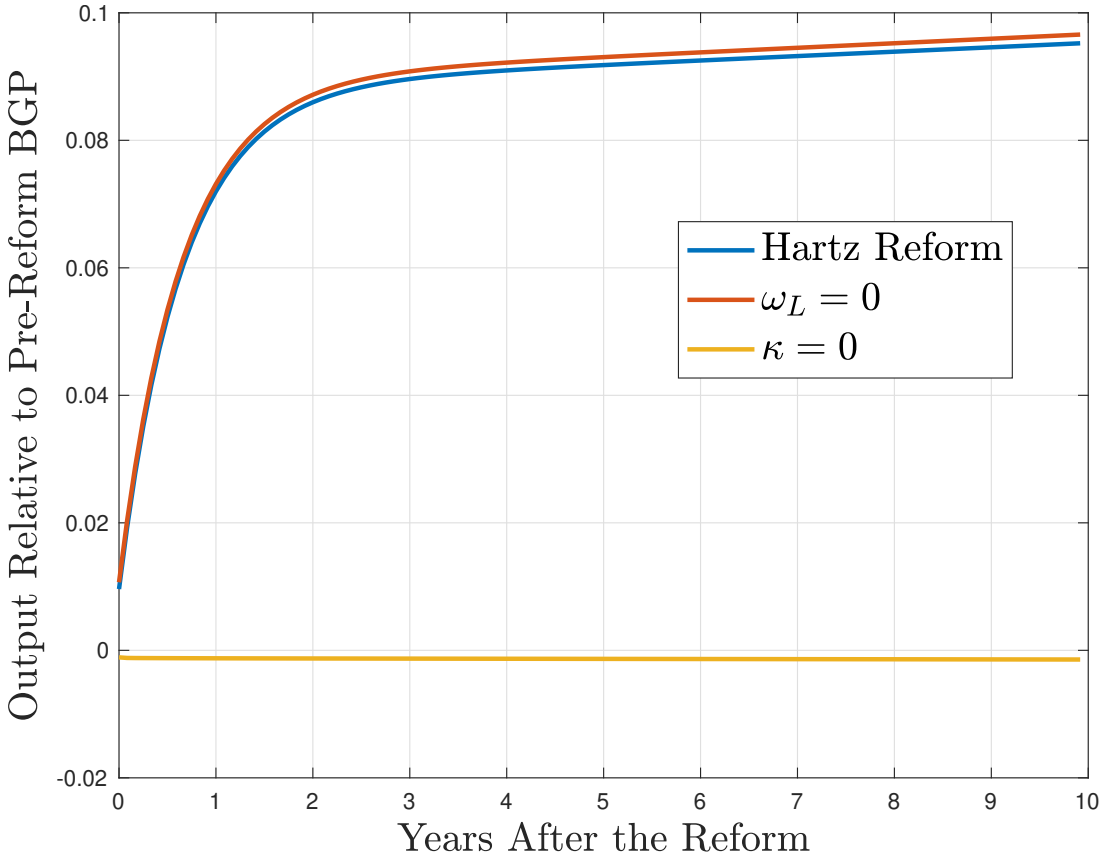
The Hartz Reform: Transition

- Smooth increase/decrease in labor supply/wage.



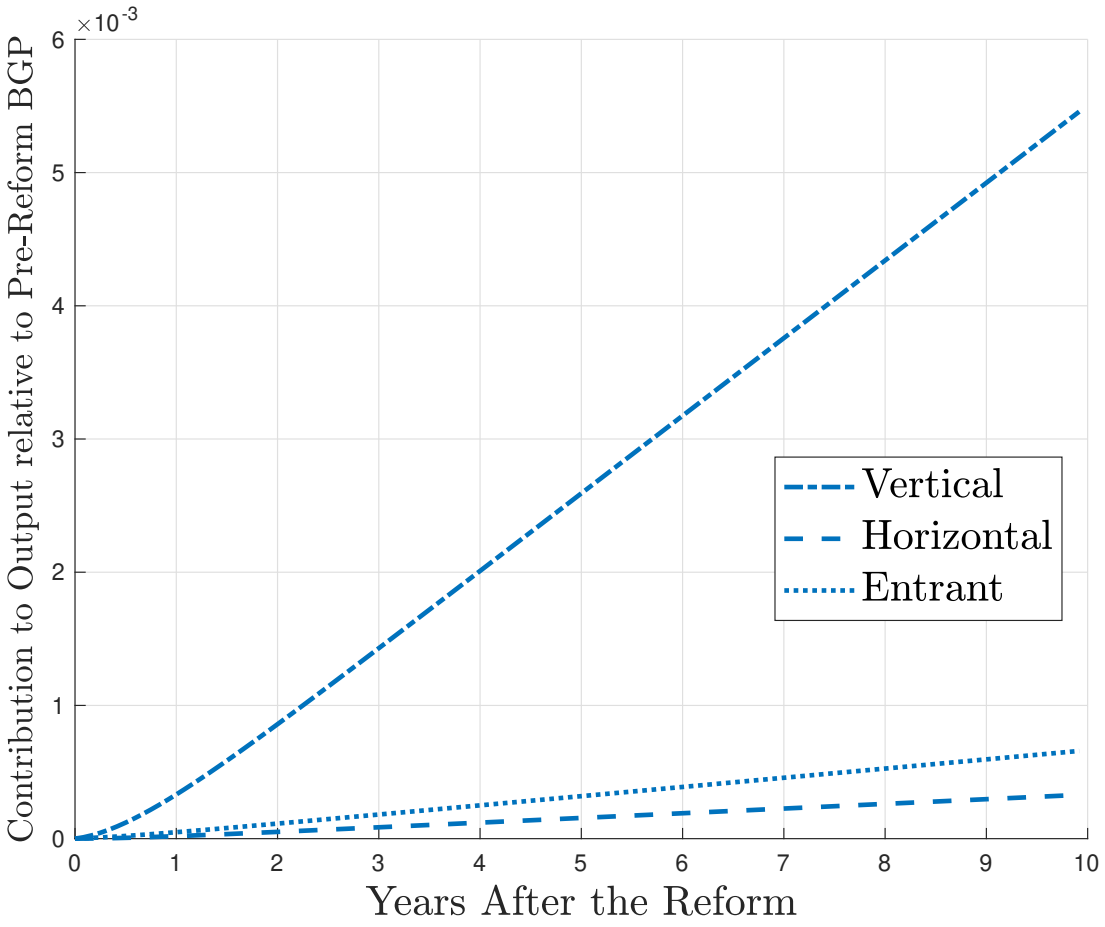
The Hartz Reform: Transition

- The labor supply margin contributes to output growth.



The Hartz Reform: Transition

- Vertical innovation makes a noticeable difference in productivity growth.



The Hartz Reform: Transition

- Job creation $\Uparrow$, but job destruction $\Downarrow$ relative to the pre-reform BGP.

	$\omega_L = 0$	$\kappa = 0$	Post
Δ% Job Creation Rate at $t = 6$	345.4%	-0.6%	345.5%
Δ% Job Destruction Rate at $t = 6$	-29.3%	-2.3%	-29.3%
Δ% Job Creation Rate at $t = 36$	1.3%	-0.6%	1.4%
Δ% Job Destruction Rate at $t = 36$	-8.5%	-2.4%	-8.6%
Δ% Job Creation Rate at $t = 120$	1.2%	-0.6%	1.3%
Δ% Job Destruction Rate at $t = 120$	-0.5%	-2.4%	-0.6%

The Hartz Reform: Transition

- Additional productivity gr. = 1% permanent $\Uparrow$ in consumption.
- Vertical innovation = 85% of all dynamic gains.

	$\omega_L = 0$	$\kappa = 0$	Post
CEV	6.05%	-0.18%	5.87%
$\Delta Y_0/Y_0^{BS}$	1.07%	-0.11%	0.97%
Δg_0^{verti}	0.80%	0.05%	0.83%
Δg_0^{horiz}	0.06%	-0.02%	0.05%
Δg_0^{entr}	0.15%	-0.06%	0.10%
ΔL	-3.22%	-0.04%	-3.27%

Concluding Remarks

- A new survey-based measure of establishment-level innovation for economic analysis.
- A quantitative quality ladder model with vertical and horizontal innovations encapsulates new facts established from the new measure.
  - Horizontal innovation generates more job flows.
  - However, vertical innovation accounts for most of economic growth.
- The model is used to quantify the aggregate implications of labor market reform in Germany through incumbent innovation.
  - Labor market reform also promotes a long-run productivity growth.
  - Most welfare and growth gains come from additional vertical innovation.
  - ⇒ Faster productivity growth but no increases in job destruction rates.

Appendix

Variables in IAB-BP

- Establishments are asked whether they implemented the following innovation activities in the previous year.
  - Process innovation: improve the production process
  - Quality improvement: improve the products they previously produced
  - Product expansion: start to offer a product that previously existed in the market
  - Variety creation: start to offer a product that did not exist in the market
- Vertical innovation includes process innovation and quality improvement while horizontal innovation includes product expansion.

Variables in IAB-BP

- Establishments are asked whether they implemented the following innovation activities in the previous year.

	Quality Improv.	Product Expansion	New Variety	Process Innov.	Any Innov.	N. Est.
All	31.01	20.09	5.76	11.77	39.70	91,823
Small	23.01	14.82	3.36	7.09	30.72	10,363
Medium	27.18	16.80	3.80	9.20	34.78	11,263
Large	38.60	23.56	7.95	16.61	47.94	42,670

Definitions of Outcome Variables

- The survey has information on extensive establishment-level variables
  - Employment as of June 30, # of hiring in the fist half of the year, # of separation in the first half of the year, Labor expenses as of June, Investment last year, Business volume last year, # of training participation in the first half of the year
- Definitions of Outcome Variables
  - Employment growth = $(AdmEmp - L.AdmEmp)/(\frac{1}{2}AdmEmp + \frac{1}{2}L.AdmEmp)$
  - Wage, Revenue, Investment growth rates are defined similarly.
  - Hiring rate = $2 \times Hiring/(\frac{1}{2}AdmEmp + \frac{1}{2}L.AdmEmp)$
  - Separation rate = $2 \times Separation/(\frac{1}{2}AdmEmp + \frac{1}{2}L.AdmEmp)$
  - Training Rate = $2 \times \#ClassParticipation/(\frac{1}{2}AdmEmp + \frac{1}{2}L.AdmEmp)$
  - Establishment age = Survey Year - Year of Foundation

Definitions of Outcome Variables - Continued

- The variables are further defined by the following.
  - $AdmEmp$ = Employment of an establishment as of June 30 in the survey year from the administrative data
  - $Hiring$ = Total number of newly hired workers in the first half of the survey year from the survey
  - $Separataion$ = Total number of separated workers in the first half of the survey year from the survey
  - $Wage$ = Imputed mean daily wage as of June in the survey year from the administrative data
  - $Revenue$ = Business volume in the previous year from the survey
  - $Investment$ = Sum of investment expenditures in the previous year from the survey
  - $\#ClassParticipation$ = Total number of participants or cases of participation in internal or external training courses the establishments cover the expenses in full or in part

Dynamic Correlation - Specification

- Variables of interest, Y_{it}:
  - Employment growth rate $= (Emp - L.Emp)/(\frac{1}{2}Emp + \frac{1}{2}L.Emp)$
  - Wage growth rate $= (Wage - L.Wage)/(\frac{1}{2}Wage + \frac{1}{2}L.Wage)$
  - Employment and wage variables come from the administrative data.

Other Variables Descriptive Statistics

- Consider the following dynamic correlation model.

$$Y_{it} = \sum_{s=-5}^{5} \mathbf{1}_{it+s}^{a} \beta_s^a + \gamma' X_{it} + \varepsilon_{it}$$

where $\mathbf{1}_{it}^{a}$ is indicator of innovation type $a =$ vertical or horizontal.

- Controls: Other types of innovation, establishment and year f.e..

! Entrant/exiting firms are excluded.

Innovation and Non-Innovating Establishments

- The panel regression specification, $j(i)$ for sector and t for year

$$Y_{it} = \beta^V L.V_{j(i)t} + \beta^H L.H_{j(i)t} + \gamma' X_{it} + \epsilon_{it},$$

Controls include fixed effects, lagged size, HHI, industrial emp. growth.

Comparison between Survey and Patent Measures of Innovation

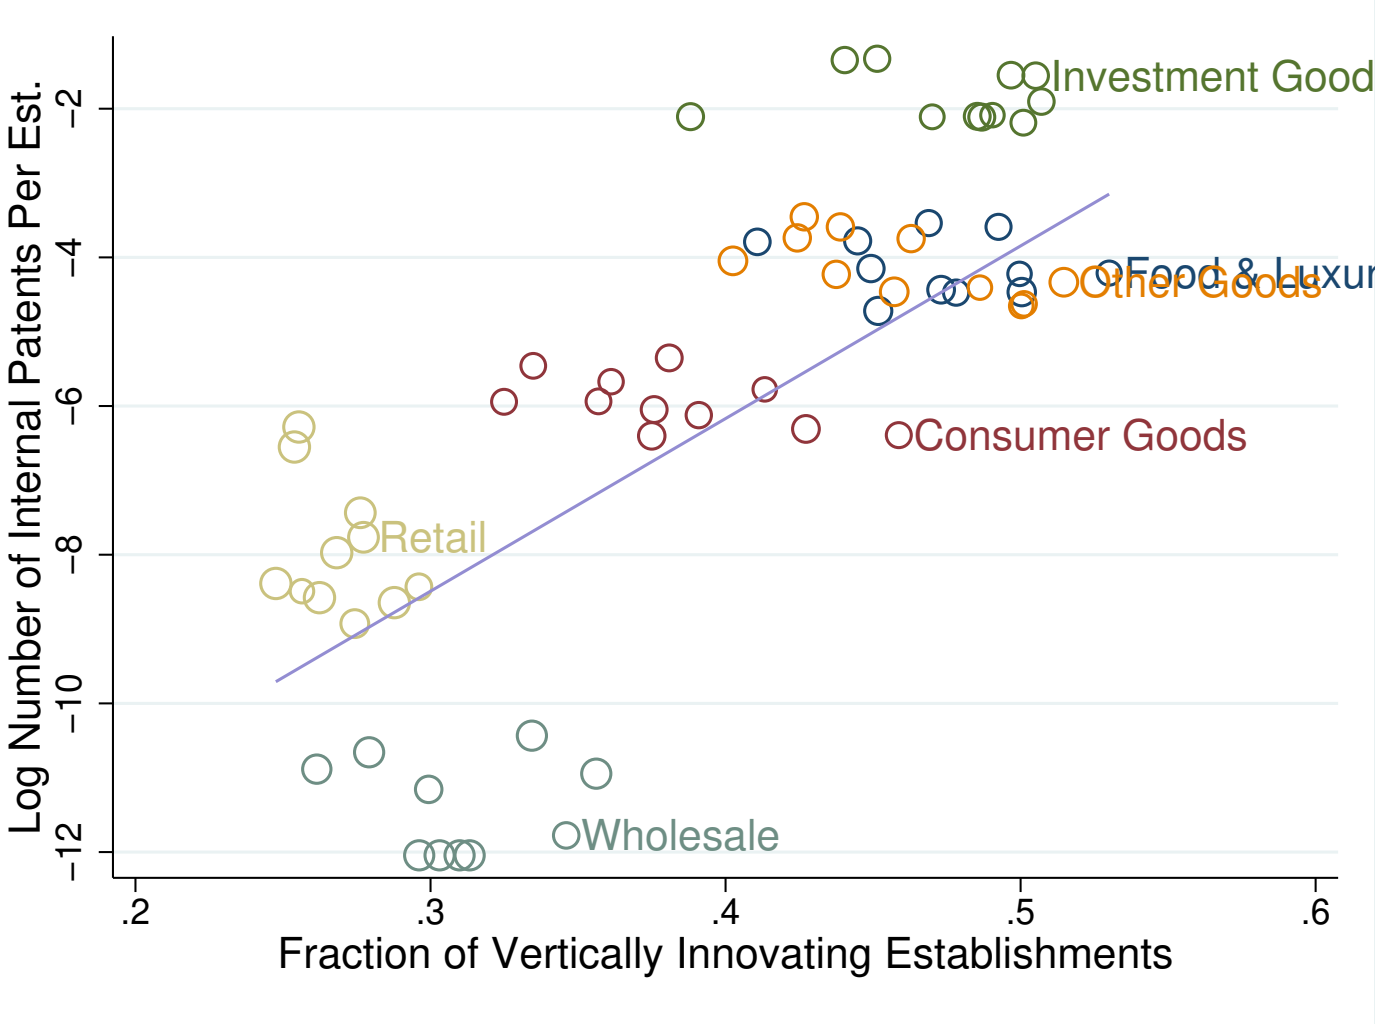
- Construct industry-year level innovation measures using the number of patents granted to German entities.
- Distinction between internal vs. external innovation (Akcigit and Kerr, 2018)
  - **Internal Innovation**: self-citation share ≥ 0.5
  - **External Innovation**: self-citation share < 0.5
- The number of patents does not even exist for agriculture, mining, construction, and service industries.
- Overall survey-based fraction of innovating establishments are strongly positively correlated with the number of patents across different industries and years.

Overall Innovation

- Fraction of either vertically or horizontally innovating establishments vs. the total number of patents

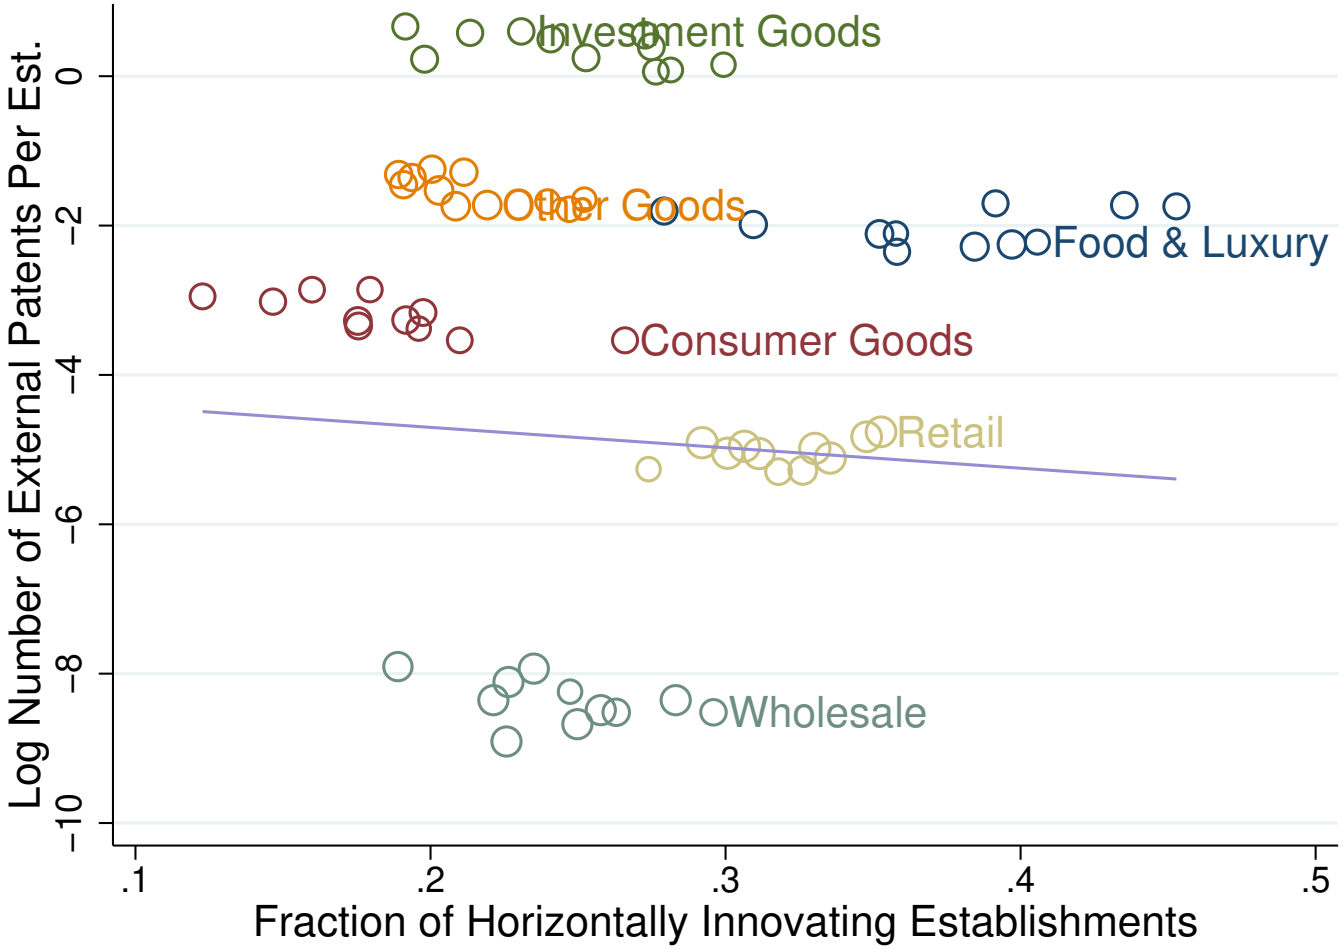
Vertical Innovation vs. Internal Innovation

- Fraction of vertically innovating establishments vs. the total number of internal patents

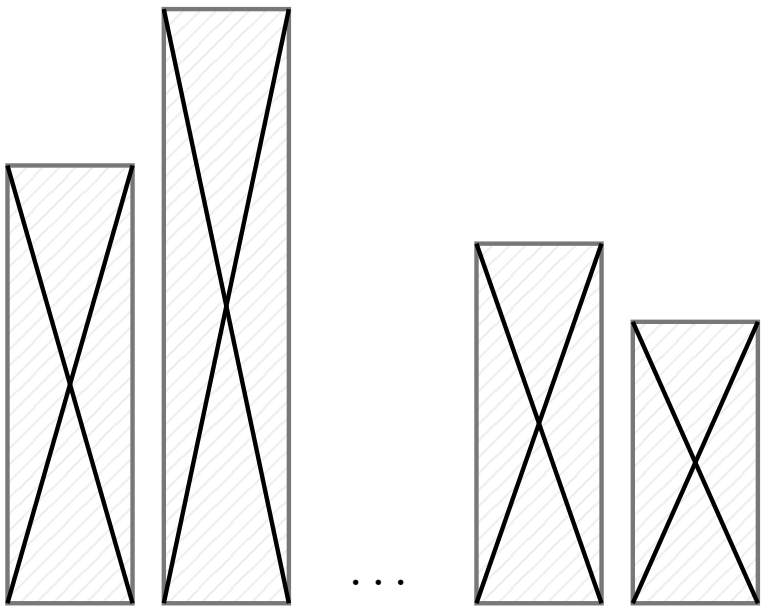


Horizontal Innovation vs. External Innovation

- Fraction of horizontally innovating establishments vs. the total number of external patents

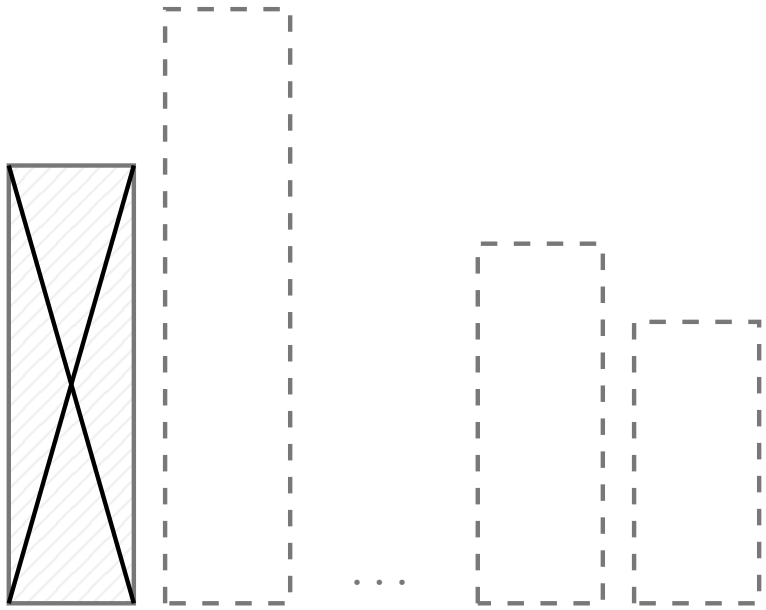


Graphics: Firm Exit



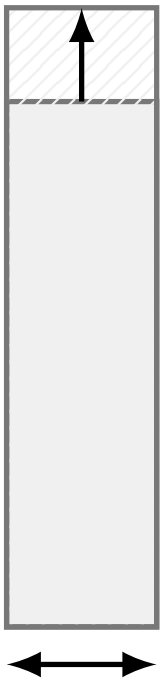
- A firm exits the market in two cases.
  1. Exogenously with rate δ.
  $\Rightarrow$ Product lines held by exiting firms are reallocated toward expanding & entering firms.
  2. The firm loses the last product line by creative destruction.

Graphics: Firm Exit



- A firm exits the market in two cases.
  1. Exogenously with rate δ.
  $\Rightarrow$ Product lines held by exiting firms are reallocated toward expanding & entering firms.
  2. The firm loses the last product line by creative destruction.

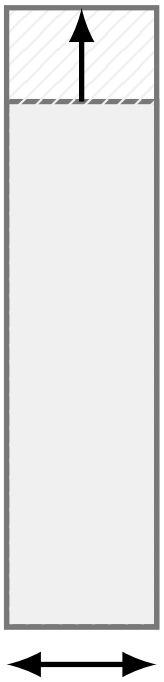
Graphics: Firm Entry



$$\Delta x = \lambda^e \bar{x}$$

- An entering firm is undirectedly matched to a product line to learn and makes vertical innovation with a constant step size $\lambda^e \bar{x}$.
- With probability p, it is matched to a vacant product line.

Graphics: Firm Entry

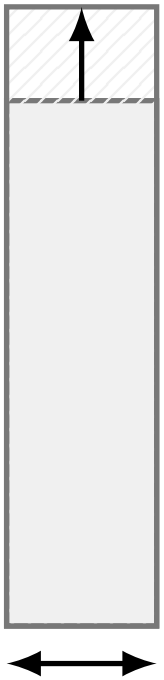


$$\Delta x = \lambda^e \bar{x}$$

- An entering firm is undirectedly matched to a product line to learn and makes vertical innovation with a constant step size $\lambda^e \bar{x}$.
- With probability p, it is matched to a vacant product line.

Go back

Graphics: Firm Entry



$$\Delta x = \lambda^e \bar{x}$$

- An entering firm is undirectedly matched to a product line to learn and makes vertical innovation with a constant step size $\lambda^e \bar{x}$.
- With probability $1 - p$, it is matched to an occupied product line.
- It replaces the existing firm only if it is more productive.

Go back

Distribution

- The distribution of product lines across x satisfies

$$g_x x f(x) = \delta F(x) + \int_{s \in (x - \lambda^i \bar{x}, x]} \xi(s) dF(s) + (1-p)(G(\infty) - G(x))F(x) - pG(x)$$

  where M is the number of the product lines.

- The distribution of expanding product lines is characterized by

$$G(x) = \int_{s \leq x} \zeta(s) dF(s) + \int_{s \leq x - \lambda^e \bar{x}} \chi dF(s).$$

- $\bar{x} := \int x dF(x) = \int_\Omega x_i di = 1.$

Go back

Creative Destruction

- The creative destruction rate is then

$$\tau(x) = (1-p)\left(\chi\left(\int_{s>x-\lambda^e\bar{x}} dF(s)\right) + \int_{s>x} \zeta(s)dF(s)\right).$$

- The probability of being matched to a vacant line, p, is characterized by

$$\delta = Mp\int \zeta(s)dF(s) + \chi p.$$

Go back

Free Entry and Labor Market Clearing

- The free entry condition is given by

$$wc_{\chi}(\chi) = \chi \left(\int (p + (1-p)F(x + \lambda^e \bar{x}))v(x + \lambda^e \bar{x}) dF(x) \right)$$

  where $c_{\chi}(\chi)/\chi$ is increasing in χ.

- The labor market clearing condition is expressed as

$$wL = \frac{\sigma - 1}{\sigma} + w \int_0^1 c_{\xi}(\xi_{jt}) dj + w \int_0^1 c_{\zeta}(\zeta_{jt}) dj + wc_{\chi}(\chi)$$

Go back

Representative Household

- Suppose all the workers pool their income together through a perfect consumption insurance.
- The representative household maximizes the following lifetime utility.

$$\max_{C_t, L_t} \int_0^\infty e^{-\rho t} \left(\log(C_t) - \frac{\phi L_t^{1+\frac{1}{\eta}}}{1+\frac{1}{\eta}} \right) dt$$

subject to

$$C_t + \dot{b}_t = W_t(1-\tau_L)L_t + \int \pi_{jt} dj + r_t b_t + \tau_L W_t \tilde{L}_t$$

- On the BGP, $C_t = Y_t$ grows at the common rate g_Y, $w_t := W_t/Y_t = w$ is constant, and the first order condition becomes

$$r_t = r = \rho + g_Y$$
$$\phi \left(L_t\right)^{\frac{1}{\eta}} = \frac{W_t(1-\tau_L)}{C_t} = w(1-\tau_L)$$

- Zero net supply of real bonds, $b_t = 0$, $\forall t$.

Go back

Aggregate Productivity Growth

- The growth rate on the BGP can decomposed into

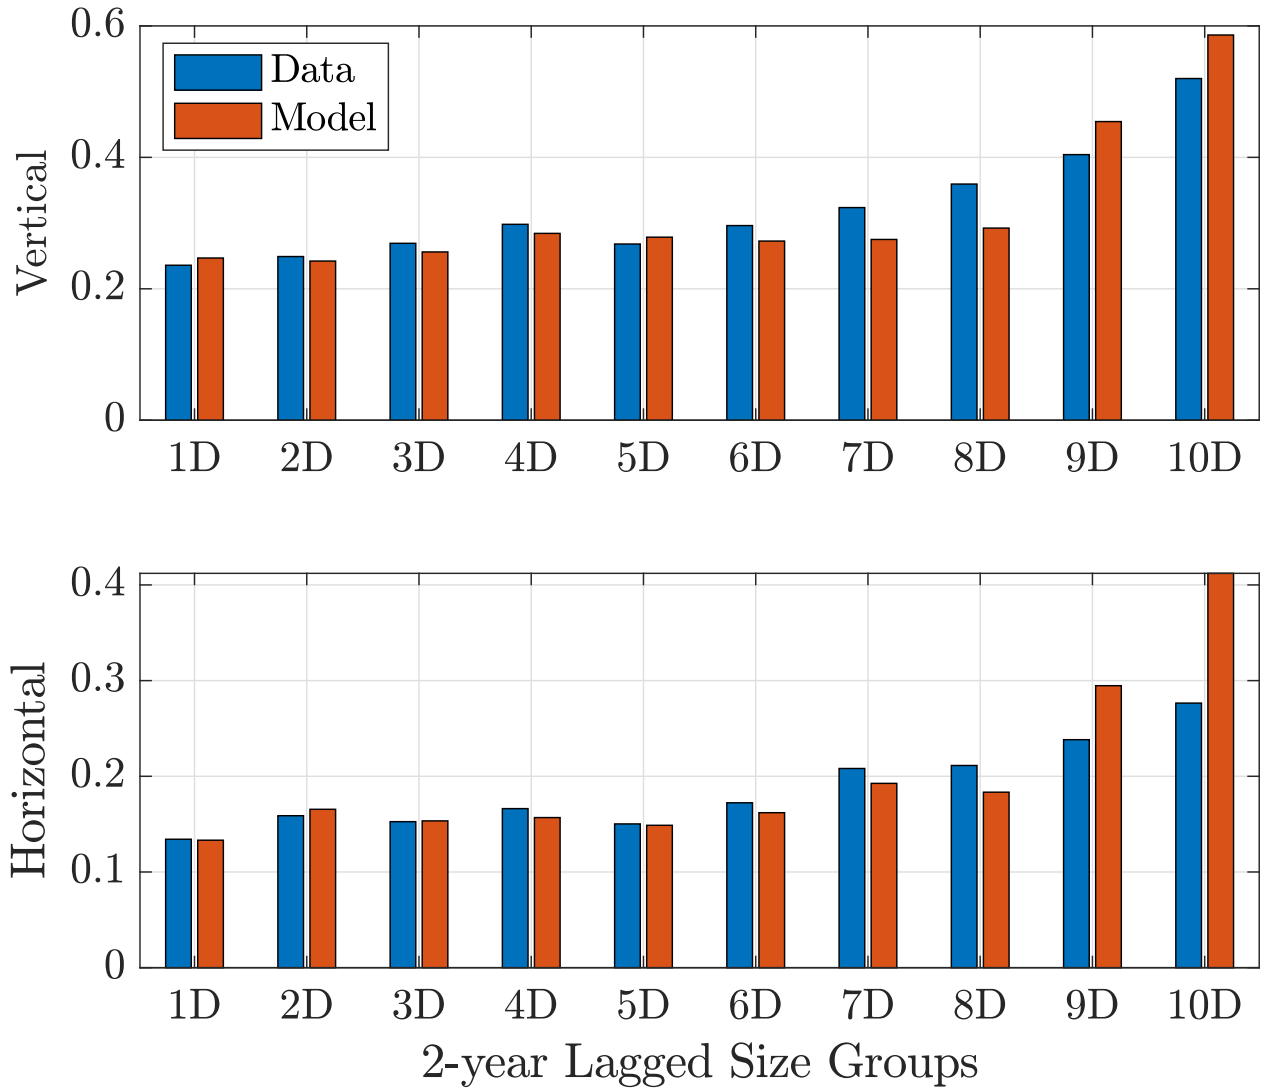
$$
\begin{aligned}
g_x \bar{x} = & \underbrace{\int \left[\int_{s \in (x-\lambda^i \bar{x}, x]} M\xi(s) dF(s) \right] dx}_{\text{vertical innovation}} \\
& + p \underbrace{\int \left[\int_{s>x} M\zeta(s) dF(s) \right] dx - p\bar{\zeta}\bar{x}}_{\text{horizontal innovation (1)}} \\
& + p \underbrace{\int \left[\chi - \chi \int_{s \leq x-\lambda^e \bar{x}} dF(s) \right] dx - p\chi\bar{x}}_{\text{entrant innovation (1)}} \\
& + (1-p) \underbrace{\int \left(\int_{s>x} M\zeta(s) dF(s) \right) F(x) dx}_{\text{horizontal innovation (2)}} \\
& + (1-p) \underbrace{\int \left(\chi \int_{s>x-\lambda^e \bar{x}} dF(s) \right) F(x) dx}_{\text{entrant innovation (2)}}
\end{aligned}
$$

where $\bar{\zeta} := \int \zeta(s) dF(s)$ is the average horizontal innovation rate.

Go back

Model Fit for Untargeted Moments

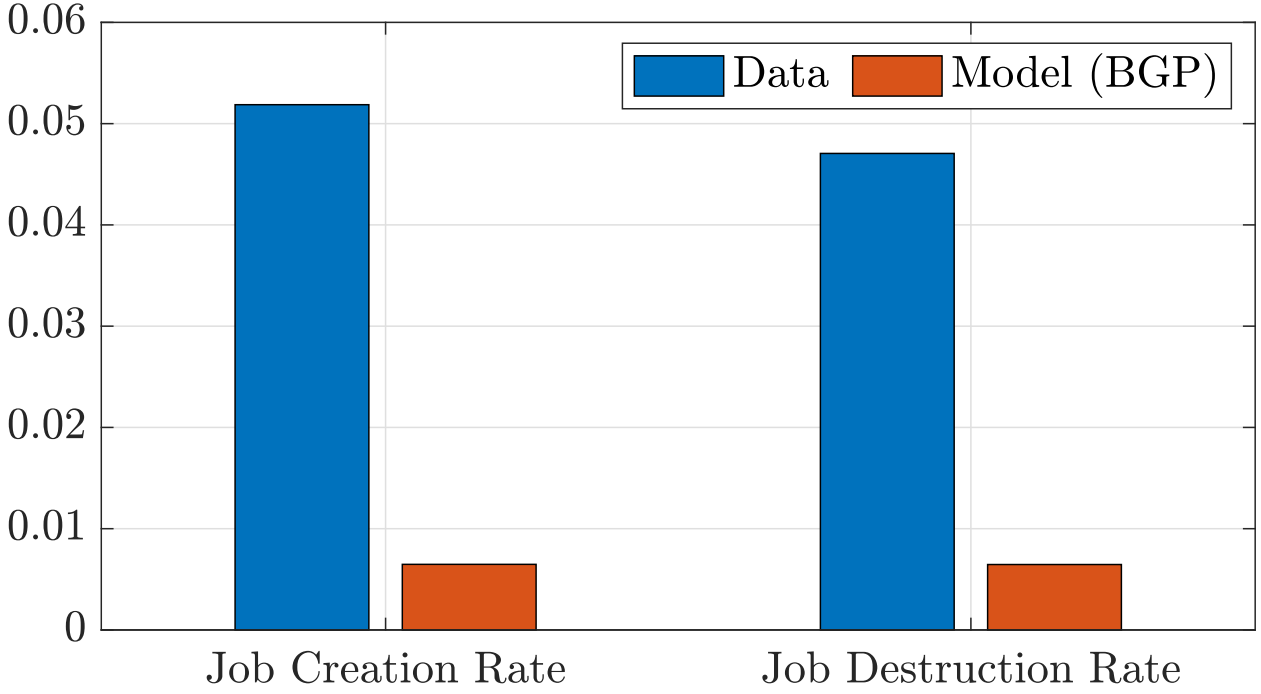
- Model fit is overall good except on the largest establishments in 10D.



Go Back

Model Fit for Untargeted Moments

- Model account for 12-15% of job turnover rates in the steady state.



Go Back

Model Fit for Untargeted Moments

- Model replicates turnover rates decreasing in size, but with a lower degree for job creation rates.

Job Dest. Due to Creative Dest.	13.15%	20.68%
Job Dest. Due to Obsolescence	29.05%	3.77%
Job Dest. Due to Exog. Exit	57.80%	75.55%
Verti. Innov. Contri. to Growth	90.84%	-
Horiz. Innov. Contri. to Growth	2.80%	16.65%
Entrant. Innov. Contri. to Growth	6.36%	83.35%

The Hartz Exercise without Vertical Innovation

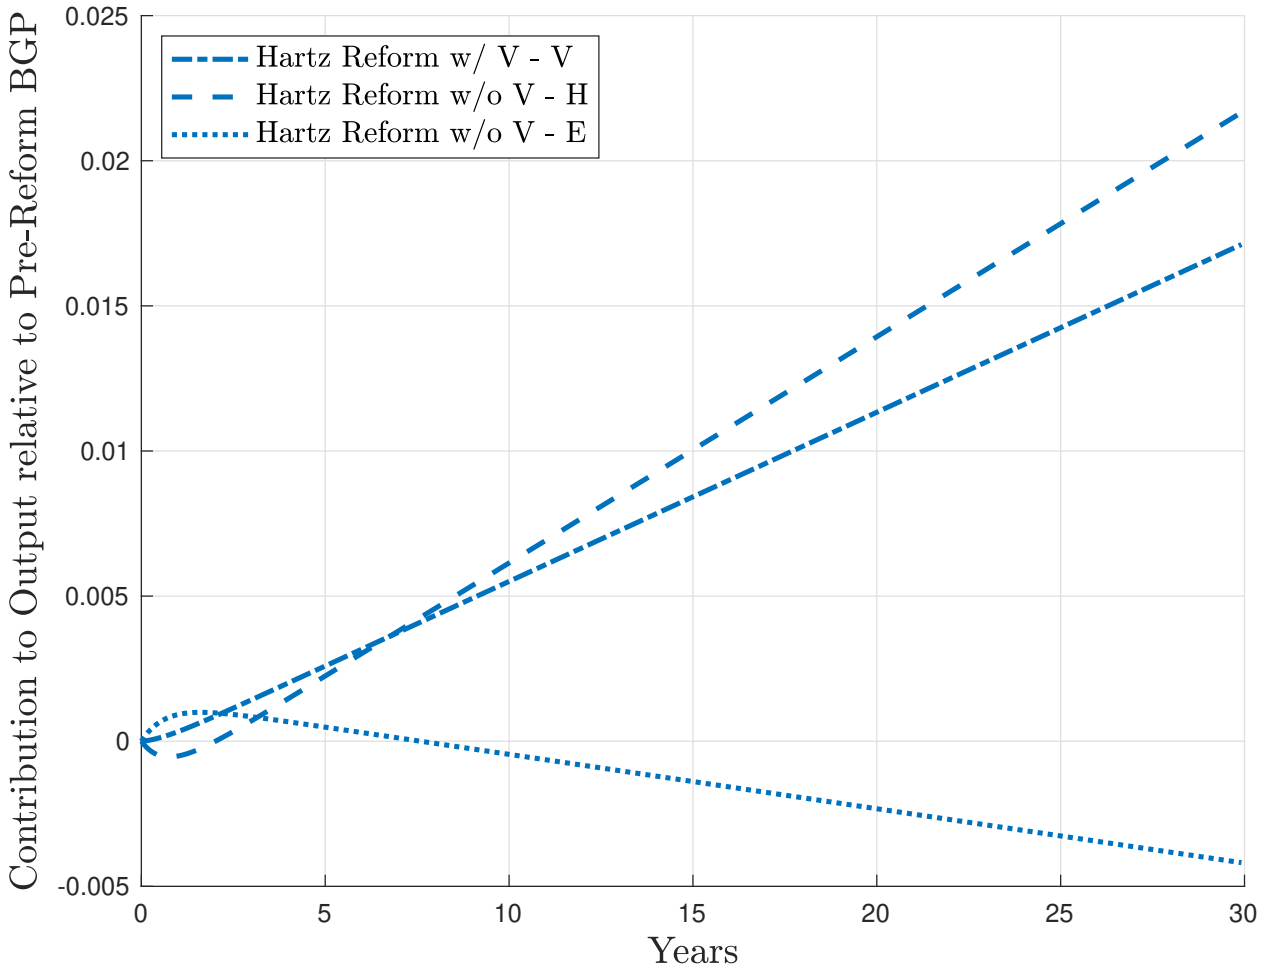
- Match the same S-S decrease in wage after the reform with and without vertical innovation.
  $\Rightarrow$ The same innovation cost reduction
- Without vertical innovation, the model predicts an increase in reallocation.

Moment	Baseline	Without V.I.
Δ Output Growth Rate	0.070ppt	0.068ppt
Δ Wage	-0.0981	-0.0982
Δ R&D Labor Share	-1.82ppt	-0.07ppt
Δ% Avg. Job Reallocation Rate	-0.17%	0.54%
Δ Avg. Annual Vertical Innov. Freq.	0.83ppt	-
Δ Avg. Annual Horizontal Innov. Freq.	0.01ppt	0.01ppt

The Hartz Exercise without Vertical Innovation

- Increase in productivity from horizontal innovation, but canceled out by the entrant innovation margin

⇒ Similar productivity growth over the transition path



The Hartz Exercise without Vertical Innovation

- Without vertical innovation, a much smaller decrease in job destruction in the SR, an increase in job destruction in the MR.

	Baseline	Without V.I.
Δ% Job Creation at $t = 6$	345.5%	594.5%
Δ% Job Destruction at $t = 6$	-29.3%	-3.7%
Δ% Job Creation at $t = 36$	1.4%	15.9%
Δ% Job Destruction at $t = 36$	-8.6%	-3.7%
Δ% Job Creation at $t = 120$	1.3%	4.2%
Δ% Job Destruction at $t = 120$	-0.6%	2.1%

The Hartz Exercise without Vertical Innovation

- Smaller welfare gains from productivity growth.

	Baseline	Without V.I.
CEV	5.87%	7.44%
$\Delta Y_0/Y_0^{BS}$	0.97%	-2.41%
Δg_0^{verti}	0.83%	-
Δg_0^{horiz}	0.05%	1.00%
Δg_0^{entr}	0.10%	-0.14%
ΔL	-3.27%	-1.32%
